 normal man the composition and volume of the fluids are almost constant. Hence the urinary output of water, sodium, and chloride (the three main components of the extracellular fluid) and also of urea (the electrolyte of the cells) must be closely related to the intake.

FIRST TYPE OF DIURESIS

The response to the drinking of water, and the path through which the kidney is stimulated, have been extensively studied (Verner 1929, 1946, 1947, Pickford 1947, O'Connor 1947, Harris 1948). The chain of events

absorbed water lowers the concentration of electrolyte in the blood.

Osmoreceptors in the region of the internal carotid artery transmit impulses to the posterior pituitary. Secretion of antidiuretic hormone into the blood is increased.

The kidney eliminates more water and less sodium, chloride, and potassium (temporary "diabetes insipidus").

Response is prompt: the diuresis starts 15 minutes after the water is drunk, and usually the whole amount is eliminated within 3 hours. Drinking, or venous injection, of hypertonic saline, eliciting the chain of events but with opposite effects, interrupts later diuresis.

A variation in the secretion of antidiuretic hormone is highly effective in maintaining the normal electrolyte concentration of the body fluids. But since the posterior pituitary reaction affects the output of water and electrolyte in opposite directions (Eggleston and Smith 1946, Harris and Roberts 1949) regulation of the volume of body fluids by this mechanism may disturb normal osmotic pressure. Thus in patients with an increased output of water with a concomitant increased output of electrolytes must raise the concentration of electrolytes in the body fluids. The result will be, and also an increased secretion of antidiuretic hormone which restricts further excretion of water. However, as soon as the patient has free access to water he will drink as much as he has lost by the diuresis. Secretion by the posterior pituitary does not depend on the osmotic pressure of the blood. Drinking alcohol has the same effect as drinking of water (Eggleston and Smith 1946), while acetylcholine (Pickford 1949), morphine and nicotine (Burn et al 1945), pain (Hall 1949), and emotions promote secretion of antidiuretic hormone. Clinical observations suggest emotions can also provoke a water diuresis.

SECOND TYPE OF DIURESIS

The volume of the extracellular fluid is probably regulated by a second type of diuresis, characterised by combined output of water, sodium, and chloride. Though it is not yet fully understood, there is abundant evidence for, and no evidence against, the following chain of events:

Absorption of water, plus equivalent amounts of sodium and chloride, increases the average plasma volume and average venous pressure.
 The average cardiac output rises.
 The kidneys eliminate more water, sodium, and chloride.
 There is no important change in potassium output.

The response is often slow, and also depends on the metabolic needs (muscular exercise, increased basal metabolic rate, fever).

One of us (Borst 1936, 1938a and b, 1941), observed that in patients with massive haemorrhage from peptic ulcer the excretion of the three components of the extracellular fluid was related to the volume of circulating blood so long as this was too low, the kidney retained water and sodium chloride, even in the presence of oedema and of an extraordinarily high sodium and chloride level in the blood. (The high sodium and chloride was due to liberal administration of saline solution, which overcompensated the loss of water through evaporation and "osmotic" diuresis). The patients who had no free access to water suffered from severe thirst. As the concentrations of urea, creatinine, potassium, and phosphates in the urine were exceptionally high, the suppression of sodium chloride excretion and the reduction of water output could not be attributed to renal insufficiency. Even an injection of a mercury diuretic had hardly any effect. The sodium, the chloride, and the water were not excreted until the blood volume was increased, either by blood transfusion, by an infusion of gum acacia, or (in case of spontaneous recovery) by post haemorrhagic dilution of the blood.

Wherever cardiac output is decreased, a similar retention of sodium chloride and water is found. In these cases a high level of sodium and chloride in the blood can be produced by rigid restriction of the intake of water. It could be demonstrated not only in dehydration but also in nephrotic oedema and oedema due to congestive heart failure. Accordingly, we postulated that the output of water, sodium, and chloride depends on the cardiac output, if the heart is normal it depends (according to Starling's law) on venous pressure, and ultimately mainly on the volume of circulating blood (Borst 1938a and c, 1941, Majoor 1942).

We regard this retention of extracellular fluid, whenever the cardiac output is low, as a homeostatic reaction essential for preserving life. In the presence of a low serum albumin level it must lead to oedema; in the presence of heart failure it must lead to an increased blood volume and high venous pressure, but even these results, though they have undesirable side-effects, are useful in that they help to prevent the cardiac output from falling too low.

The above hypothesis is in keeping with the following facts. In nephrotic oedema, gum acacia injections, by increasing plasma volume, produce a strong saline diuresis (Peters 1935, Lepore 1937). The same response can be obtained with any agent that produces a long-lasting increase in blood volume. In a patient with Laennec's cirrhosis, Veening (1937) precipitated a saline diuresis by reinjecting her own ascitic fluid intravenously. In young men with nephrotic oedema large blood transfusions resulted in a sharp rise in venous pressure, as long as venous pressure remained high, the output of water and chloride was much increased. In one case the elimination of extracellular fluid was more than 1 litre in an hour (Borst 1948). In heart failure, saline diuresis is known to be the most reliable sign of a good response to digitalis. Paroxysmal tachycardia is sometimes accompanied by diuresis, sometimes by oliguria. In this disease we discovered that the diuretic response of the kidneys was a saline diuresis, different from the response of the same patients to the drinking of water. One patient had short attacks, which were accompanied by saline diuresis, and we found that the circulation-time was always slightly but definitely diminished, pointing to an increased cardiac output. When the tachycardia continued, the heart was obviously enlarged, the venous pressure rose on slight exertion, and the circulation time became gradually longer. This was

associated with a decrease in water and sodium chloride output (Borst 1948, de Vries et al 1950)

We may expect that in normal man, too, the output of extracellular fluid will depend on cardiac output. Intake of water with an equivalent amount of sodium and chloride will not change the concentration of the electrolytes in the blood, but the volume of blood-plasma and the venous pressure will rise. It is interesting to note that, in physiological as well as in pathological conditions, the diuretic response to an increased cardiac output tends to be much slower than the response to the drinking of water. The same is true of the reduction of water and sodium chloride excretion which follows reduction in cardiac output. The duration of a change in the circulation is probably as important as its magnitude, when the change is small it must last some time before there is much response from the kidneys. The increased output of extracellular fluid following intravenous injection of digitalis glycosides seldom begins within an hour, and may not begin for several hours, though the increase in pulse pressure and the fall in venous pressure are often already at their maximum within three quarters of an hour. Likewise in patients who have had haemorrhages or in patients with nephrotic oedema the diuretic response to a blood-transfusion is often considerably delayed.

An unusually long delay is seen in patients who develop urticaria after transfusion. This may be explained by a temporary decrease in the total volume of circulating blood after the transfusion, because the volume of plasma lost into the weals exceeds the volume of the transfused blood. This is demonstrated in fig 1, presenting the data for a patient who was treated for severe anaemia and slight hypalbuminaemic oedema. She lost no blood during the period of observation, and received only milk at regular intervals, and accordingly the excretion of water and chlorides followed the diurnal rhythm we shall later describe. During the transfusion severe urticaria developed lasting several hours. The haemoglobin rose steeply to a level higher than was anticipated, and the venous pressure exhibited a slight decline. When the weals disappeared the haemoglobin level gradually decreased from 11.1 to 8.9 g per 100 ml, showing that the increase in blood volume must have been 25% in 24 hours. Parallel with the blood dilution the output of water and sodium chloride increased.

A delay in diuretic response of more than 12 hours, not due to plasma loss, was seen by one of us (Borst 1936) in a case in which a large transfusion was followed by a febrile reaction, and similar observations have since been made many times. When in administering digoxin or strophanthin some fluid is injected paravenously, the diuretic response often remains in abeyance so long as the local inflammation is accompanied by fever. The sodium retention found during infectious diseases is probably of the same type.

In two patients with lobar pneumonia and in three patients with peritonitis (Borst 1948) we found a total suppression of sodium chloride output and a high sodium and chloride level in the blood. The pulse pressure and the pulse rate were high, in one case the urica clearance rose to 150% of the normal average, in another case it rose to 250%. The cardiac output and the renal blood flow must have been high, there was no anaemia and no aortic incompetence. Large transfusions, combined with intravenous injection of 5% glucose, elicited a marked but brief saline diuresis. Obviously a rise in cardiac output resulting from fever, or from change in metabolism related to fever, does not give rise to a saline diuresis, usually sodium chloride and water are retained. The reduction in urinary output is not related to increased extrarenal fluid loss, for it starts before a significant amount of fluid can have

been lost by evaporation. It is found in patients with chloride balance disturbance.

The forcible heart failure induced by strenuous muscular exercise is also followed by oliguria and salt retention (Eggleston 1943). On the other hand, a change from standing to the recumbent position, resulting in a 33% rise of cardiac output (McMichael and Schaefer 1944) without an increase in metabolic rate, often causes a saline diuresis (Ni and Rehberg 1931).

Merrill and Cargill (1947) found that in latent heart failure the elimination of sodium chloride was impaired during rest, but fell sharply during exercise. In hyperthyroidism complicated by heart failure, sodium chloride excretion might be low in the presence of a cardiac output higher than normal. A decrease in metabolic rate was accompanied by a elimination of chlorides.

Warren and Stead (1944) noted that in patients with heart failure sometimes a considerable retention of water, sodium, and chloride, associated with marked blood dilution, preceded the rise in venous pressure. They concluded that this retention was primarily renal and was related to a reduction in cardiac output. Their observations are still open to debate, because exact recording of venous pressure by the method of Mont and Tabora is difficult, but their conclusion is generally accepted.

THIRD TYPE OF DIURESIS

Water diuresis and saline diuresis, with their physiological counterparts, do not explain all the variations in the output of urine. Of great significance also is

Fig 1—Blood transfusion followed by urticaria. Plasma loss causes temporary excessive rise in haemoglobin and delayed the diuretic response.

and type of diuresis, connected with the diurnal rhythm

Quincke (1877) pointed out that urinary output is appreciably higher by day than by night, and that it rises promptly in the morning if the subjects stay awake after having passed urine. In 1893 he reported that patients with heart or kidney diseases often have the peak of diuresis during the night. Wilson (1889) had noticed that whereas in most patients the diurnal rate of excretion of water and solids is far higher than the nocturnal, in cases of debility the two rates of excretion approximate, especially in cardiac disease and even more in organic renal disease.

Campbell and Webster (1921, 1922) found that the excretion of chlorides and urea was also highest during the day, but creatinine excretion remained more or less at the same level. When the subjects slept in the daytime, working and taking food and fluid at night, the rhythm was not reversed. Jores (1933), repeating the experiments with people accustomed to night work, confirmed these results.

Simpson (1924, 1926), Norn (1929), Gerritzen (1940), and Smits (1947) studied subjects lying in bed and receiving exactly the same food and water at regular intervals during the day and during the night. The urinary output per hour of chlorides (and, in the cases where it was determined, of sodium and potassium) showed a regular tide, the lowest output being found between 9 P.M. and 4 A.M. and the highest between 7 A.M. and 4 P.M. The lowest figures were one third of the highest. The diurnal variation in the output of water, though following the same course, was not as regular as the diurnal variation in the output of the electrolytes. According to Norn, the differences between day and night are greatest for the output of potassium, but there were no fluctuations in serum potassium. Magnesium output had its peak during the night, and calcium output was independent of diurnal rhythm.

Gerritzen, who found appreciable fluctuations in the output of urea and only slight variations in blood-urea, expressed the view that urea production by the liver and urea excretion are coordinated.

Simpson showed that in some of his subjects sleep decreased the output of water and chlorides during the day, in the majority the diurnal rhythm was not influenced by sleep in the daytime.

Smits found a reversed rhythm in two patients with heart failure and in four out of six patients with cirrhosis of the liver, they had the highest output of water and chlorides during the night. In one case, in which sodium and potassium were determined, sodium excretion varied like that of chlorides, but potassium excretion was the same by day and by night.

PRESENT INVESTIGATION

In the present study we examined, during a total of 500 days, the urine of fourteen male and four female patients, who emptied the bladder 8 times a day, exactly

at midnight, 3 A.M., 6 A.M., &c. Great care was taken to avoid loss of urine during bowel movements. After having passed urine, the patients drank an exactly measured amount of milk and water and ate one or two biscuits with butter. The three-hour rations remained the same throughout the experiment.

In one patient, suffering from attacks of paroxysmal tachycardia, but having otherwise a normal circulation, we collected 65 × 8 urine samples. All were measured and examined for chlorides, and for urea plus ammonia, creatinine was determined only for 42 days. Average figures for the output in successive three-hour periods are presented in Fig. 2.

One patient, suffering from peptic ulcer of the lesser curvature (described in detail by Molhuysen et al. 1950) received, during part of the observation period, a supplement of 5 g sodium chloride and 8.4 g bicarbonate divided into 8 equal parts daily. The urine became alkaline and contained virtually no ammonia. In this case we determined also the sodium and potassium (flame photometer). Since the patient received during part of the observation period a treatment that would disturb the rhythmic output, the average figures presented are taken only from days for which this interference need not be considered.

Figs 2 and 3, which are representative for several other cases, show clearly that under the described conditions water and potassium output are at midnight nearly 50% of the amount excreted at midday. During the night the output of chloride and sodium falls to approximately 33% of the highest daytime amount.

Since the difference between the elimination of urea by day and by night depends on the flow of urine in the tubules of the kidney, a higher output during the day was to be expected. On calculating the supposed output at an excretion rate of 1 ml per minute, according to van Slyke's formula for the standard clearance, the averages for the corrected figures show only insignificant

† When the intake of electrolytes is excessive the percentage difference during day and night is less impressive.

Fig 2—Diurnal urinary output of water and chloride and of urea and ammonia (average of 65 days, Jan. 16 to March 21) also diurnal urinary output of creatinine (average of 42 days).

Fig 3—Diurnal urinary output (averages of two 10-day periods in December and January). The chart on the right shows the average figures for the days when a supplement of 5.0 g sodium chloride and 8.4 g sodium bicarbonate was given and the urine was free from ammonia.

fluctuations. When bicarbonate is used and no ammonia is excreted, there is a slight fall in urea output during the first part of the night, following the period of higher diuresis. In patients not receiving bicarbonate, an increase in the ammonia excretion during sleep probably just compensates for this small reduction in urea output. The output of creatinine remains constant, not only in the average figures but even in the individual ones. The fluctuations beyond 20% of the mean are exceptional, and bear no relation to diurnal rhythm (Molhuysen et al 1950).

The diuresis related to diurnal rhythm is characterised by a simultaneous rise in the output of water, sodium, chloride, and potassium—i.e., both intracellular and extracellular fluid—and cannot be mediated either by the pituitary or by increased cardiac output. It represents a fundamentally different type of diuresis.

DIURNAL RHYTHMS

The rhythmic excretion of urine is only one of the diurnal variations of the organism. Rhythmic variations in body temperature have long been recognised, and a diurnal rhythm of carbohydrate metabolism, reflected in a high blood glucose level in diabetics during the night, is shown to exist independently of food intake and sleep (Forsgren 1929, 1934, Ekman and Holmgren 1949, Gerritzen 1940, Möllerstrom 1943). Probably there are also diurnal rhythmic fluctuations in the blood eosinophils, the highest figures being found at night (Rud 1947).

It is tempting to attribute all these rhythmic changes to a rhythmic secretion of adrenocortical hormones of the 17-hydroxy corticosterone type. Though, in the treatment of rheumatoid arthritis, Compound E promotes retention of extracellular fluid and excretion of potassium, just as deoxycortone does (Perera et al 1949, Sprague et al 1950) in short lasting experiments, in certain circumstances Compound E enhances the output of sodium chloride and potassium (Thorn et al 1941, Ingle et al 1945, Dorfman 1949), it raises the blood-sugar level, and reduces the number of eosinophils, it increases uric acid excretion, while creatinine excretion is unchanged (Forsham et al 1948).

A patient with typical Addison's disease, receiving the standardised diet and deoxycortone injections (2 mg at midnight, at 6 A.M., at noon, and at 6 P.M.) still showed the rhythmic excretion of water and electrolytes, but the variations were far less conspicuous than in other patients who followed the standardised diet (fig 4). For comparison we present the figures of a normal man lying in the same wards during the same period, and receiving the same diet, with the addition of 8 biscuits, 2 g of sodium chloride, and 400 g of water daily. Probably the patient with Addison's disease had still some functioning adrenocortical tissue, for the decline in plasma volume following withdrawal of deoxycortone was self limiting and no crisis developed (see Molhuysen et al 1950), but the reaction to adrenocorticotrophic hormone was absent. The diurnal rhythm is caused by alternation of day and night. The relative importance of daylight and of the change from sleep to waking cannot easily be determined, and the delay between stimulus and response is not known. Some of our observations suggest that the increase in the output of water and electrolytes after waking and becoming exposed to daylight may be prompt and of the same magnitude as the responses in the other types of diuresis. It is difficult to reverse a rhythm completely by a reversal of routine (Jones 1933), probably the diurnal rhythm, like any other rhythmic phenomenon, tends to outlive its cause. However on a boat going from east to west the peak of excretion is every day one hour earlier, remaining at the same hour on local time (Joslings 1940).

At a meeting of the Netherlands Society for General Pathology on April 1, 1950, Gerritzen presented data of three subjects who were exposed to artificial daylight during the night and were in the dark during the day. This régime resulted in duplication of the rhythm in excretion of water and chlorides, the two maxima being at noon and at midnight. In a fourth subject, who looked directly into the lamp during the night, the rhythm was completely inverted by three dark and three light nights.

The data presented in figs 2 and 3 were obtained in winter. In winter as well as in summer the light in our wards is reduced, and no conversation is allowed from 8 P.M. till 6 A.M., at which time the nurses start work and all the patients are awake. Accordingly from 9 P.M. until 6 A.M. the urinary output is low. Only one patient, a young woman, was studied at the height of summer, and in this case the output of chlorides in the period between 3 A.M. and 6 A.M., and especially between 6 A.M. and 9 A.M. was much higher than during winter, whereas from 9 P.M. to 3 A.M. it was regularly as low as one third of the output during the peak of diuresis (fig 5). This result may be explained by the fact that the window curtains do not prevent daylight from entering the wards in the early morning. The variations in potassium elimination in this case are also striking. The difference between day and night output is far greater than usual, the ratio being 4 to 1, or nearly the same as found by Norh (1929) in experiments on himself.

Fig. 4.—Diurnal urinary output (averages of the 7 days March 18-25). Left: normal subject. Right: patient with Addison's disease. The normal subject's diet differed by the addition of 8 biscuits and 20 g sodium chloride. Owing to the use of sodium bicarbonate the urine contained only traces of ammonia.

on himself. Unfortunately No does not mention the time of the year. We found that the pattern of chloride excretion of three patients studied in March and April, and one studied in September, was between the summer and winter type (fig 4 right hand side).

CHARTS—AND DEDUCTION FROM THEM. By recording the diurnal rhythm in schematic form, nearly every diuresis can be produced by diuretic drugs can be attributed to one of the three types or to a combination of them. For this purpose

however, the hourly intake and output of food, fluid, and electrolytes must be known, as well as the temperature, body-weight, venous pressure, arterial pressure, heart rate, and blood haemoglobin, which sometimes must be estimated several times a day. Also the daily recording of all the information on charts must be constantly under the eyes of the workers interested in the case, and especially of the nurses, to enable them to see at a glance the relation in magnitude and time of all the findings. Inevitable mistakes are then traced without delay and often can be redressed, or, when this is impossible, at least repetition on subsequent days is avoided. Furthermore we have found that the facts are far better understood when the findings for a recent period are presented.

We have therefore simplified the methods as far as possible and have avoided complicated procedures, believing that rapid information on a great many points is often more useful than more detailed information on one point obtained by tricky and time consuming methods. Our methods are described elsewhere (Borst 1948, Molhuysen et al 1950).

Problems supposed to be very complex often turn out to be simple when an overwhelming number of data can be collated graphically on one chart. Van Slyke, Smith, Albright, and their co workers, and other investigators, have long used these methods with striking results. Unfortunately every problem needs its own type of recording, and to those unfamiliar with the key, the large charts, with so many blocks and curves, may seem at first to increase the difficulties.

Fig 5—Diurnal urinary output of water and chloride (average of 7 days), potassium (2 days), and urea plus creatinine (4 days) in a patient.

As we usually want to compare the data of a large number of cases, even the amount of wall space available for charts may decide whether an important problem is rapidly solved or not. In our hospital the wards which are out of use because of the lack of nurses have proved highly convenient for displaying our figures.

The reversed rhythm found in some patients with heart-failure and cirrhosis of the liver could be explained when their charts were compared with those of patients showing a normal rhythm. In cases of gastric ulcer, water and chloride excretion sometimes decreased when the patients who had been recumbent for some time were propped up on cushions. Viersma and ten Holt (1950) studied a patient with postural hypotension who was having the standardised diet. Raising the head of the bed by 40 cm resulted in a sharp fall in blood pressure, accompanied by a long-continued reduction in water and sodium chloride excretion to 30%, the reduction in the output of potassium was slight and did not disturb the pattern of rhythmic excretion.

In heart failure and in cirrhosis, where there is increased pressure in the portal vein, the venous return is abnormally dependent on the position of the patient. One of our patients with Laennec's cirrhosis showed a normal rhythm as long as we insisted on complete recumbency. Thereafter he arranged his pillows in such a way that he was semirecumbent during great

Fig 6—Effect of position in bed on the output of water and chloride in a case of cirrhosis of the liver. Continuous complete recumbency ended at the point marked by the arrow.

parts of the day and was continuously recumbent only at night. From that moment (marked in fig 6 with an arrow) the output of water and chloride was irregular, the highest output being found during the night (fig 6). The same change could be demonstrated in a patient with heart failure of moderate severity. Probably the contrast in excretion of extracellular fluid and potassium, found by Smits in the case described above, was also due to the semirecumbent position during the day.

In severe heart failure we found the elimination of extracellular fluid often lower in recumbency than in the upright position. This must be due to a decrease of the output of the overburdened heart, as could be expected from Starling's law and as has been shown by McMichael and Sharpev Schafer (1944b).

In the patient with paroxysmal tachycardia the rhythm was interrupted by an enormous excretion of water, and (to a lesser extent) of sodium and chloride, at the beginning of an attack. When the tachycardia continued for several hours the regular rhythmic output was resumed. During an attack lasting several days and treated with quinidine in high dosage, heart failure developed, the elimination of water and chloride was depressed but strictly rhythmic, the lowest excretion being found during the night. The patient was lying quietly recumbent all the time.

A patient with the nephrotic type of glomerulo-nephritis, having massive oedema and ascites and a urea-clearance of 17%, was in nearly the same semirecumbent position during day and night. The output of chlorides was low, but showed a regular and normal rhythm, with the maximum during the day. Large blood-transfusions, resulting in a rise of the abnormally low venous pressure, increased the output of both water and chloride, but the diurnal rhythm was undisturbed and continued on a higher level.

THE KIDNEY AND DIURESIS

The mechanism of the renal response in the three types of diuresis is only partly known.

It has been demonstrated that water diuresis does not depend on the glomerular filtration-rate and is due to depression of reabsorption by the tubules.

In the diurnal excretory rhythm the figures for urea and creatinine suggest a relatively constant glomerular filtration-rate, while the fluctuations in the output of water, sodium, and chlorides (the components of the extracellular fluid) and of potassium are due to variations in tubular reabsorption.

Only in the second type of diuresis is the evidence for a purely tubular mechanism inconclusive. Merrill (1946) and Mokotoff et al. (1948) demonstrated that low cardiac output in heart-disease was associated with a reduced renal blood flow and glomerular filtration-rate. Merrill and Cargill (1947) also found that the retention of sodium chloride in their patients with heart-failure was always associated with a reduction of the glomerular filtration-rate by more than 30%. From analogy with what is known about the reabsorption of glucose, they assumed that the reabsorption of sodium chloride continued at the normal rate, with the result that there was a sharp reduction in its excretion.

As the level of endogenous creatinine in the blood is (over not too long periods) constant (Blumgart et al. 1934), creatinine output in successive urine specimens can, as a relative measure for creatinine clearance, be compared to chloride excretion in the same urine specimens (Catheter specimens from the bladder are unnecessary). Furthermore, when fluctuations of blood urea are minimised by a standardised intake, as can be checked by one or two blood-urea determinations daily, analysis of the urine specimens is sufficient to show any gross variation in urea clearance over the day. A great many observations in patients and normal subjects have demonstrated that creatinine output and urea-clearance are closely related.

Nearly always a sharp decrease in urea-clearance and creatinine output, resulting from circulatory disturbance, is accompanied by a much more pronounced decrease in the output of chlorides and sodium, but the two decreases do not run parallel. Chloride excretion may remain low or may be decreased in spite of a rise in creatinine output and urea-clearance. Total suppression of sodium chloride excretion often continues for some time after recovery from a long lasting serious impairment of the circulation when urea clearance has already risen to normal values (Borst 1936, 1938a). During fever, all sodium and chloride may be retained, in spite of an excessive urea clearance (to 250% of normal) and in the presence of high sodium and chloride levels in the blood. In heart-failure or in nephrotic oedema an improvement in the circulation often produces a lengthy saline diuresis, while a rise in urea-clearance and creatinine excretion is absent or lasts only a short time (Borst 1948).

On the basis of these facts we think that in patients with a low cardiac output there are two mechanisms, wholly different in character but finally leading to the same result: (1) hyperfunction of the renal tubules causes a selective retention of extracellular fluid, and (2) reduction of the glomerular filtration rate reduces the excretion of all urine constituents, including water and sodium chloride. The second mechanism is probably the less important.

SUMMARY AND CONCLUSIONS

Three fundamentally different types of diuresis and their physiological counterparts can be distinguished:

- 1 Diuresis of water
- 2 Diuresis of water plus sodium chloride (extracellular fluid)
- 3 Diuresis of water plus sodium chloride plus potassium (extracellular plus intracellular fluid)

Respectively these are the response to the drinking of water, to an increased cardiac output, and to the change from night to day as part of the diurnal rhythm.

The elimination of water, sodium, chloride, potassium, urea, and creatinine has been studied in eighteen patients receiving, over a total of 500 days, 8 equal amounts of milk daily, given at 3 hourly intervals. During winter the output of water and the three electrolytes was highest from 9 A.M. to 3 P.M. and lowest from 9 P.M. to 6 A.M. The ratio for sodium was 3 to 1, for water and potassium it was 2 to 1. In summer (one case) the peak for water and electrolytes was from 6 A.M. to 9 A.M., and the lowest excretion was from 9 P.M. to 3 A.M. In spring and autumn the pattern of excretion was between the two extremes.

The average excretion of creatinine and urea (corrected for diuresis) is independent of the diurnal rhythm and shows no important fluctuations. This points to a more or less constant glomerular filtration rate during the 24 hours of the day, the variations of diurnal excretory rhythm being dependent on variations in tubular reabsorption. The available evidence, though inconclusive, points to the same mechanism for the

saline diuresis, the glomerular filtration being at of minor importance.

In a patient with Addison's disease a normal excretory rhythm was found, but the ratio between the output during day and night was only 3 to 2.

The diurnal rhythm may be reversed in cirrhosis of the liver and in moderate heart-failure when the patients are recumbent at night and semirecumbent during day, so that venous return is reduced. The reverse is especially in excretion of water and sodium.

Invaluable assistance in this work was given by the and the laboratory staff. The ward nurses A. van and W. L. E. Sipskes were responsible for the supervision of the diets, the collection of excreta, and the weighing of patients. Miss E. Knol made the calculations and plotted the figures, Miss J. van Daaelslaar made the flame photometer determinations, and the other determinations largely done by Miss L. Quelle, Miss E. Mollema, M. Buitenhuis, Miss F. Wellinghof, and Miss D. Doyer.

THE EFFECT OF SPLANCHNICECTOMY ON RENAL FUNCTION

A IAN L MAITLAND

VRD, MB Glasg FRFCS, FRCSE

ASSISTANT SURGEON, WESTERN INFIRMARY, GLASGOW

THE manner in which thoracolumbar sympathectomy achieves its beneficial effect in hypertension is not fully known. Corcoran and Page (1941) have shown that the renal blood flow is unaltered by the operation. Consequently there is a tendency to regard the effect as due to the capacity of the denervated blood vessels to dilate and so absorb the excess pressure. An alternative or parallel view is that the effect is obtained partly by this dilatation and partly by breaking the chain between the hypophysis and the kidney through the only link accessible to surgery. An important result of the work of Corcoran and Page has been to direct attention away from changed conditions in the kidney.

Trueta et al (1947) have shown that the shunt mechanism which they describe in the kidney may considerably alter the distribution of the blood flow through that organ without materially changing the total volume apparently traversing its vessels. They have also shown that this mechanism is under the control, and may be brought into action in animal experiment by stimulation of the nerve supply to the kidney. When it is recalled that Peet's procedure represents the minimum, Smithwick's the optimum, and Grimsom's the practical maximum ablation of the sympathetic ganglia necessary to ensure a preganglionic denervation of the kidneys, it seems possible that part of the benefit from these operations may be due to some redistribution of the blood flow within the kidney. As any effect of this kind would be demonstrable by an alteration in the composition of the urine obtained before and after the operation, I have investigated a small series of hypertensive patients before and after the first stage of a bilateral splanchnicectomy, and 5 of these have now been followed for over a year.

METHOD

The initial investigation into separate renal function consisted in intravenous pyelography and renal analysis, the latter only was repeated, usually three weeks after the first splanchnicectomy. The method of differential renal analysis favoured has already been described (Maitland 1949). The patient receives no fluid for five

hours before the examination and is limited in intake from the evening before. The specimens are obtained from the bladder at cystoscopy and from each kidney through ureteric catheters. The renal specimens are collected for a suitable period in graduated tubes. At the end of this time the wastage to the bladder is collected as the catheters are withdrawn and their tips lie on the trigone. This wastage is measured separately, but if 6 F whistle tipped ureteric catheters are used it rarely exceeds 1 ml. Experience gained from carrying out this form of investigation in 150 patients with various renal lesions has shown that, for studies such as this, the volume of urine collected from each kidney, the pH, and the urea content provide adequate data for comparison. Before this conclusion was reached, creatinine estimations were also made, but they were discontinued when no significant difference in the behaviour of the two substances had been found in 15 cases. The pH is estimated by the BDH 'Capillometer,' and the urea in a 'Doremus' ureometer by the hypobromite method using a tuberculin syringe and a curved needle to deliver the urine to the ureometer.

The results obtained from these admittedly primitive clinical methods of investigation into renal function in 7 cases are detailed in tables I and II.

The actual figures obtained are presented in table I. In table II the standard urea clearance values calculated from the figures in table I are related to the blood pressure at the time and in 5 cases which have been followed for periods between a year and eighteen months have also been correlated with the late result of the treatment.

CASE RECORDS

Each case is discussed individually before any attempt is made to group the results in any way.

Case 1—Male aged 52. Seen on May 19, 1948. For a year had had headaches of increasing severity with two severe hypertensive crises, six and four months ago. Recently the headaches had been very severe accompanied by vomiting and quite uncontrolled by sedatives. There had also been dizzy attacks but no breathlessness or swelling of the feet. Social conditions fair. Moderate smoker and uses alcohol.

Examination—Well built young looking man. Heart normal in size. Blood vessels sclerosed. Blood pressure (B.P.) 205/115 mm Hg. Sedation test B.P. went to 180/110 in three hours. Eyes no fundal change other than those of arteriosclerosis. Urine normal. Blood urea 31 mg per 100 ml. Intravenous pyelogram normal.

Operation and Progress—June 16, 1948. Right Smithwick type sympathectomy. June 25 B.P. 170/100. No headaches since operation. Oct 22 B.P. 196/140, well and back at

TABLE I—FIGURES OBTAINED AT RENAL ANALYSIS BEFORE OPERATIVE TREATMENT AND AFTER FIRST STAGE

In case 4 where the volume obtained from the right kidney exceeded 1 ml per minute the standard clearance was calculated to maintain uniformity

work July 1949 B.P. 210/140, having severe cardiovascular symptoms

This man had a wide pulse pressure and generalised arteriosclerosis. He suffered from extremely severe headaches which were quite uncontrolled by medical treatment. The intravenous pyelograms were normal and the optic fundi showed the changes of arterio-sclerosis without retinitis or papilloedema. Splanchnicectomy was therefore done on one side only, in order to relieve the headache, which it did. The renal efficiency dropped by an amount roughly proportional to the diminution temporarily obtained in the blood pressure, and the late result was bad.

Case 2 (Mr W. Arthur Mackey's case)—Female aged 30. Seen May 21, 1948. For fifteen months had had very severe frontal headaches affecting vision with blurring of the right eye. Two normal confinements. Social conditions fairly good.

Examination—Healthy looking small thin woman. Blood vessels not sclerosed. Heart not clinically enlarged. B.P. 210/130. Optic fundi discs normal, patch of exudative retinitis in left eye but none in right eye. The usual changes in the vascular pattern. Urine sterile and free from albumin. Blood urea 36 mg per 100 ml. Intravenous pyelograms and straight X-ray films—no renal abnormality.

Operation and Progress—May 24, 1948. Right Smithwick sympathectomy. June 3 B.P. 150/105. Dec 21 symptom free. B.P. 180/120 standing, 170/110 lying. Left Smithwick sympathectomy. Nov. 16, 1949. Symptom free, B.P. 160/100.

This woman had typical essential hypertension with no history of renal disease, her symptoms were headaches and visual upset of fifteen months' duration. Intravenous pyelograms were normal. The optic fundi showed normal discs with a patch of exudative retinitis in the left eye. At the first renal investigation her right kidney stopped secreting almost completely and at the examination ten days after operation (right splanchnicectomy) her left kidney in the same way virtually ceased secreting. At this examination the right side showed some improvement in function while the function of the left kidney was less. This patient has been followed for about eighteen months. She is symptom free, and has a blood pressure of 160/100.

Case 3 (Mr Mackey's case)—Female aged 35. Seen Oct. 21, 1948. For a year she had noticed that she was easily tired and breathless. No urinary symptoms or visual

upset. For four months headaches had been severe diurnal. During pregnancy three and a half years prior B.P. had been raised, two years later a second pregnancy had been terminated because the B.P. was high, and then she had been under treatment for this complaint. Her father had died of internal hemorrhage and her mother "shocks". Social history good.

Examination—Good colour. Healthy looking well-nourished woman. B.P. 220/130. Optic fundi discs normal. No exudative retinitis. Urine specific gravity 1.010, albumin. Blood urea 45 mg per 100 ml. Straight X-ray and intravenous pyelograms—no abnormality in the urinary tract.

Operation and Progress—Oct. 25, 1948. Right splanchnicectomy. Dec 2 B.P. 150/100. Jan 6, 1949. Symptom free, B.P. 180/125 vertical, 200/120 lying. Left splanchnicectomy. Nov. 17, 1949. B.P. 240/140, dyspnoea on exertion.

This woman developed hypertension as a result of pregnancy. During her first pregnancy three and a half years before, her blood-pressure had been high and subsequent pregnancy had had to be terminated because of hypertension. She also had a bad family history, both parents having died of hypertensive incidents. The intravenous pyelograms were normal. The optic fundi showed no exudative retinitis, and the discs were normal. During both renal investigations the right kidney ceased secreting, although in the interval a right splanchnicectomy had been done. The contralateral kidney showed some slight improvement in function. The case has been followed for just over a year apart from dyspnoea on exertion, the patient is symptom free, but her blood pressure is 240/140, and the result must be classed as bad.

Case 4 (Mr Mackey's case)—Female aged 18. Seen Dec 9, 1948. Had had occasional "bilious attacks" with very severe frontal headaches, over the past year, an occasional palpitation. At an examination for superannuation, albuminuria and a high blood pressure had been found. Nothing relevant in the family history. Social conditions good.

Examination—Healthy looking well-nourished girl. B.P. 200/140. Optic fundi normal. Urine specific gravity 1.01. Bladder urine contained coliform organisms and pus cells but urine obtained from the kidneys was sterile. Intravenous pyelography—normal function, a little delay in the left side but outline normal, slight clubbing of right calices suggestive of chronic infection.

Operation and Progress—On sedation, B.P. fell to 130/110 in three hours. June 21. Right splanchnicectomy. Oct. 1. No symptoms except occasional palpitations, B.P. 160/110 vertical, 160/105 lying.

On May 28, 1950, her own doctor reports that she is well with occasional headaches. B.P. 170/110 without previous rest. The second sympathectomy has not yet been done.

This girl had been found to have albuminuria on routine medical examination, and questioning her mother revealed occasional bilious attacks during the previous year. There was no history of previous renal disease although infection was found in the bladder urine and her intravenous pyelograms suggested chronic renal infection. The renal urines were sterile and cell-free. The family history contained nothing of note, and the optic fundi were normal. There is much improvement in the function of her right kidney after the splanchnicectomy on that side, and slight improvement of the function of the opposite kidney also. The late result when the treatment is completed seems likely to be satisfactory, since there is already a significant reduction in blood pressure eleven months after the single operation.

Case 5 (Mr J. Sloan Robertson's case)—Female aged 48. Headaches for three years (occiput to vertex), worse and more frequent in recent months and accompanied by a feeling of fullness over the back of the shoulders. Some darkening of the skin of the face had been noted and puffiness of the ankles at night. For two years had been easily tired and had angina of effort and nocturia. One child aged 18 years known kidney trouble during pregnancy, but severe vomiting throughout.

Examination—Florid, full faced, rather stout woman with mented skin and severe halitosis. Teeth sound. B.P. 140/140. Urine specific gravity 1.010, sterile. Intravenous pyelograms normal function, left renal out normal, right spastic in appearance and apparently concentrating the dye.

Operation and Progress—Oct 3, 1949 right Peet's operation. Oct 20 B.P. 160/108.

This woman had had severe headaches for three years, with a feeling of fullness over the back of the neck and shoulders. Recently puffiness of the ankles had been observed. During her single pregnancy she had had kidney trouble, but had severe vomiting. The intravenous pyelogram demonstrated spasticity of the right renal pelvis. During and after this investigation she had severe right abdominal pain, which recurred after her operation (right Peet's sympathectomy). The optic fundi showed no gross changes. The renal analysis showed a very poor secretion from the right kidney before operation, with a considerable improvement fifteen days after operation, an improvement in which the left kidney participated.

Case 6 (Mr Sloan Robertson's case)—Female aged 35 for four or five years had had headaches of characteristic pressure type, accompanied by palpitation. At first they were not severe, but two years ago they had become much worse and more frequent. At that time she had had an abortion at two months and was treated with thyroid extract and sedatives. In November, 1947 she had had a syncopal attack, and her blood pressure was found to be raised. Since December, 1947, the headaches had been severe, and there had been a tight feeling in the left chest. In 1937 one child had died ten days after birth. Two children aged 9 and 6, were alive and well. Social conditions reasonably good.

Examination (April 27)—Florid obese woman. Pulse rate 100, heart-sounds pure. B.P. 220/140. Blood urea 15 mg. per 100 ml. Radiograph of the chest shows enlargement of the heart. Fundus of right eye engorged veins, abnormal arteriovenous crossings, haemorrhages, exudate and fuzziness of the disc margin. Left optic fundus similar changes, but the disc was clearer, though with some exudative retinitis.

Operation and Progress—May 4, 1948 left Peet's splanchnicectomy. May 14 B.P. 160/120. May 19 right Peet's splanchnicectomy. Sept 9 1949 B.P. 140/100. Dec 1 symptom free, B.P. 160/100.

This woman had five years' history of headaches and palpitation, initially not severe but worse after a miscarriage two years ago. Raised blood-pressure had not been observed until five months ago. She had no history of renal disease, and no toxæmia had been noted during her three pregnancies. The intravenous pyelograms showed no abnormality. The optic fundi showed exudative retinitis on both sides and some papilloedema of both discs. The renal estimations done before and after a left Peet's sympathectomy showed a remarkable difference in the ability of the left kidney to concentrate urea after the operation. Unfortunately, standard clearance values could not be calculated, owing to the absence of the necessary blood urea. The right kidney showed at this time the same cessation of secretion noted in case 2. This case has been followed for over eighteen months and the patient is symptom free with blood pressure 160/100.

Case 7 (Mr Sloan Robertson's case)—Male aged 42. Seen June 28 1948. Nineteen weeks previously had developed influenza, since when he had had continuous frontal headache. For five weeks blurring of vision, no other symptoms. He had had acute nephritis in 1936, cholecystectomy in 1941, and appendicectomy in 1948.

Examination—Thin healthy looking man. B.P. 220/140. Optic fundi flame shaped haemorrhages and exudative retinitis, both sides. Intravenous pyelograms normal function and outline to the right kidney, function of the left a little delayed, renal pelvis spastic in type.

Operation and Progress—July 21 1948 left Smithwick splanchnicectomy. Oct 2 B.P. 200/130. Oct 11 right Smithwick splanchnicectomy. Nov 2 B.P. 190/125.

On May 10, 1949, he was readmitted because of a cerebrovascular accident, five weeks before, with permanent changes in reflex response of right leg and left facial weakness. B.P. 230/130. Intravenous pyelograms normal function and outline of right kidney, definite delay in excretion from the left kidney, the outline of which is extremely spastic. Muscle biopsy gross hydropyemia of the parietal tissues but no irreversible changes in the peripheral arterioles. The patient was discharged in August without further surgical treatment. On Dec. 6 his doctor reported "He is confined to bed, but goes out to the football match on Saturday in a wheeled chair. B.P. 170/110."

This man had a short history of headache and blurring of vision following influenza. He had nephritis twelve years before. Both optic fundi showed haemorrhages and exudative retinitis. Intravenous pyelograms revealed a spastic left renal pelvis, and the initial renal analysis showed a marked difference in the clearance values, in favour of the right kidney.

After a left Peet's sympathectomy there was considerable improvement in the function of that kidney. A year later it seemed that the result was not good, and the patient was investigated further, when an extreme degree of spasticity of the left renal pelvis was found on intravenous pyelography, similar to that shown in another patient who recovered after nephrectomy (Maitland 1949). Analysis of the renal urines showed virtually no function on that side. These findings and the result of the muscle biopsy suggested that in this case the left nephrectomy which was considered when the sympathectomy was performed might have given a better result than that operation.

The patient has made a remarkable partial recovery from this hypertensive crisis and is at present on a salt free low protein diet with restricted fluids, but the result must be regarded as bad.

DISCUSSION

Splanchnicectomy or preganglionic denervation of the kidney, in patients such as case 1, where the changes in the vascular architecture are fixed, depresses function through the lowering of filtration pressure caused by the drop in blood pressure, or has no apparent effect, as in case 3. If improvement takes place it can show in one of two ways, or possibly a combination of both. The urinary volume may increase without materially altering from the character of a glomerular filtrate, or the volume may remain much the same but the urea content rise. The first of these alterations in composition would occur if an increased number of cortical nephrons were brought into action, and the second if the nephrons in action had not increased in numbers but the function of their tubules had improved. This view is tenable whether the tubule is regarded as a site for the excretion of urea or as the site for reabsorption of water. Both of these effects have been observed in this group of cases.

A study of the figures for renal function alone in these tables reveals that in four cases sympathectomy has produced an improvement in the standard urea clearance in the denervated kidney. In a fifth case, where it was unfortunately impossible to calculate the postoperative clearance values, the figures of the analysis suggest that a similar beneficial effect on renal function has taken place.

In cases 2, 4, and 5 the increased volume of urine obtained from the kidney after sympathectomy may be regarded as presumptive evidence of increase in the number of cortical nephrons in action. Besides this increased volume in all three there is an increased urea content, indicating improved tubular function.

In cases 6 and 7 there is no significant difference in the volume excreted by the denervated kidney. There is, however, an increase in urea content sufficient to suggest an improved tubular activity in the functioning nephrons. These results are not regarded as evidence

of an increased renal blood flow, but they suggest that in some cases at least sympathectomy leads to a redistribution of the blood flow through the kidney which has a beneficial effect on function.

In the five cases followed longer than a year a correlation of the analyses with the late results demonstrates that in the two (cases 2 and 6) where the blood pressure still shows definite improvement the pattern of secretion between the kidneys had altered in a similar manner at the second analysis, the kidney still possessed of its nerve supply secreting poorly, while the denervated kidney functioned well, secreting in one case a large volume of urine and in the other a urine of higher concentration. This pattern was not observed in any of the other cases. Of the three cases which are bad results, one was not expected to be otherwise. One of the remaining two had the same complete stoppage of secretion before and after sympathectomy, the other showed only a slightly improved function as a result of denervation. This case may have been a unilateral renal hypertension and might have given a better result from a left nephrectomy.

SUMMARY

In seven cases of hypertension a differential renal analysis was done before and after the first sympathectomy.

In one case renal function diminished roughly in proportion to the fall in blood pressure, in one case no change was noted, and in the others there was an apparent improvement in renal function estimated in this way.

In 5 cases followed for a year or more an attempt has been made to correlate the results of the renal analysis with the late result of the treatment.

I have to acknowledge with thanks the generous coöperation of my colleagues Mr W Arthur Mackey, F.R.C.S., and Mr J Sloan Robertson, F.R.C.S., who permitted the urological assessment of their cases and gave me free access to their case records. Without their help in these matters this work could not have been readily completed. I have also to thank the medical superintendents of the Eastern District Hospital, Killearn Hospital, and the Western Infirmary, Glasgow, for permission to use their records, and once again to acknowledge my debt to Mr W W Galbraith for facilities in the urological clinic Western Infirmary.

AUREOMYCIN AND AMOEBIC DYSENTERY

T G ARMSTRONG A J WILMOT
 M D Camb, M R C P D M Oxf, M R C P

R FILDON DEW
 M D Edin

From the Amabiatis Research Unit, Council for Scientific and Industrial Research, King Edward VIII Hospital, Durban.

'AUREOMYCIN' was successfully used in 3 cases of amoebic dysentery by McVay et al (1949). A larger series of 38 cases, of which 27 (71%) were apparently cured, was reported by Hughes (1950) but these cases were not acute and most of them had failed to respond to other forms of treatment. Anderson and Anderson (1950) were able temporarily to clear macacus monkeys of experimental infections. Their *in vitro* experiments, like those of Bradu and Hansen (1950) suggested that aureomycin was not directly amoebicidal but acted indirectly by destroying bacteria necessary to the life of the amoeba—a view we have held in respect of this and other antibiotics.

We record below our results with aureomycin in a standard series of fifty-two African cases of acute amoebic dysentery, five African cases of exceptional severity, and four milder European cases.

MATERIAL AND METHOD

In Durban and its environs many thousands of native Africans live in overcrowded shacks without any form of sanitation. Amoebic dysentery is endemic and over 2500 cases a year are admitted to this hospital alone. The form of the disease is acute and serious with severe colonic ulceration and myriads of trophozoites in the stools. In 1946 the case mortality rate was 45%. The disease, therefore, produces large numbers of patients who may be regarded as a uniform population on which the various therapeutic agents may be tested on a large scale.

For therapeutic trials some selection of patients was necessary. For domestic reasons only males were used. All patients were complaining of diarrhoea with blood and mucus, showed ulceration at sigmoidoscopy, and had actively motile amoebae in stools or scrapings. The attack was the first in all but six of our fifty-two cases and in these six the original attack had occurred more than 12 months before we saw them. Cyst passers were not accepted for the series. Cases showing chloride deficiency, abdominal distension, sloughs on sigmoidoscopy, or signs which have been found to presage perforation or ileus, were excluded because it was thought unjustifiable to experiment on such severely ill patients.

Sigmoidoscopy was done daily until all ulcers had healed, and on the 10th, 15th, 20th, and 27th days when stool examination was also carried out both by direct and zinc sulphate flotation methods. When possible, scrapings from ulcers were examined for parasites. Results were classified into three categories.

Success—Symptom free. All ulcers healed and no amoebae found in stool examination.

Possible failure—Usually symptom free. One or more ulcers still open, but amoebae not found in stools or scrapings.

Absolute failure—Open ulcers still present and motile amoebae still demonstrable.

A study of the changing bacterial flora in some of these cases will be published later.

Follow up was attempted at monthly intervals after the completion of treatment, but, in spite of the offer of payment to those Africans who returned, the results were very incomplete.

DOSAGE

Aureomycin was given by mouth in doses of 0.25 g four times daily at 6 hourly intervals for 15 days. No other active drug was given, but from the 15th day onwards a placebo of calcium gluconate gr 5 t.d.s. was given by mouth.

RESULTS

Of the fifty-two patients, one who was apparently cured at 15 days refused further observation and discharged himself. He is accepted as a success at 20 days but is discarded from the series at 27 days because he cannot be assumed to have remained well. One patient, an absolute failure at 20 days, was removed from the series and given emetine and Iodoquin. He is included in the figures at 27 days because he may reasonably be considered to have remained a failure on this date.

Table 1 shows the results as treatment progressed. The figures at 20 days should be compared with the figures given in table 11 for a number of other drugs.

Daily sigmoidoscopy showed a remarkably rapid rate of healing. Twelve cases were completely healed by the 4th day, and at the end of 7 days no less than twenty-nine were healed. Before treatment, ulcers were nearly always

TABLE 1—RESULTS OF TREATMENT OF 52 CASES OF AMEBIC DYSENTERY WITH AUREOMYCIN

Totals	52	52	52	51

covered with mucopurulent exudate, but this soon cleared. Healing usually began at the periphery of the ulcers, but sometimes the whole surface of the ulcer appeared to acquire epithelium simultaneously in a matter of a few days. One of the striking effects of aureomycin was the normal appearance of the mucosa between the ulcers. In these acute cases the mucosa between the ulcers is usually inflamed and oedematous, and with ordinary amoebicidal drugs it takes several weeks to return to normal, with aureomycin the return to normality occurs in a few days.

Clinical improvement preceded healing by several days, and diarrhoea ceased usually after 1–2 days. No toxic side effects were noted, but the African is notoriously reticent about minor complaints.

Disappearance of amœbæ was equally rapid and dramatic. Daily examination of exudate obtained at sigmoidoscopy failed to reveal amœbæ in six cases on the 2nd day, in twelve cases on the 3rd day, and nineteen cases on the 4th day. By the 4th day, therefore, thirty seven out of fifty one cases had been cleared of amœbæ. By the 9th day all cases were free of amœbæ, with the single exception of the patient who was an absolute failure throughout. It was found in most cases that on the 3rd or 4th day the amœbæ greatly increased in size, sometimes reaching a length of 90 μ . It seemed almost as though their powers of division had been destroyed, for they usually vanished a day after the appearance of these "giant" forms. The two cases classified as "possible failure" were symptom free.

Our follow up, owing to the lack of cooperation of our patients, has been very incomplete, and full reports are not yet to hand. However, those available paint a somewhat disappointing picture. One month after discharge twenty seven of our successful patients returned. Twenty were well, free of amœbæ, and without ulceration at sigmoidoscopy. But the other seven came because they were sick, and all these were found to have ulcerated colons and large numbers of trophozoites in their scrapings. One quickly died from fulminating amœbiasis and clinical diphtheria. Three of these relapses occurred within 2 weeks of discharge, two within 3 weeks and two at 4 weeks. One patient had a hepatitis, and all, apart from the one who died, responded to emetine and diodoquin.

Seven "follow-ups" are available at 2 months, two at 3 months, and one at 4 months. All show normal bowels and negative stools. So far we have seen no relapses after the end of the first month from discharge.

FIVE SEVERE AFRICAN CASES

These patients were considered too ill to be included in the experimental series. This type of case had never before been accepted for an experimental series, because of the risk to life involved in not using a proven amoebicidal drug. But our early experiments with aureomycin tempted us to try it. In addition we had learnt that the findings at sigmoidoscopy described below meant unusual delay before healing was complete.

Three patients were found at sigmoidoscopy to have very large ulcers covered with a thick tenacious slough resembling the later stages of an ulcerated skin carbuncle. Two of these patients were dehydrated. In one, the urinary chlorides were only 20 g per litre. Treatment was the same as for the main series, but intravenous drips were given when necessary. One of these patients was free of amœbæ on the 3rd day, another on the 5th day, and the third on the 7th day. In one case all ulcers were healed on the 17th day and follow up a month after discharge showed the patient to be well, without ulceration of the colon. The second patient had open ulcers with exudate on the 20th day, though much healing had taken place and no amœbæ could be found. He was given emetine and diodoquin on the 20th day, and was healed by the 34th day. The third showed only slight improvement after 7 days of aureomycin although again no amœbæ could be found. Emetine was added to aureomycin and he made a slow recovery. Ulcers were still open on the 37th day, but on the 55th day these were found to have recently healed.

In a fourth patient the whole rectum was seen at sigmoidoscopy to be covered with a tenacious greenish-black and grey slough, which was later passed as a necrotic tubular cast of the bowel. Aureomycin cleared this patient of amœbæ and left a clear granular surface on which a stricture subsequently developed. Emetine and diodoquin were given after the 20th day, but it was many weeks before the bowel was healed. We feel that the results in these grave cases were most encouraging.

One fulminating case of amebic dysentery was treated with aureomycin in larger doses—four 250 mg capsules in 4 hours, ten capsules in 20 hours, and six in the next 24 hours. The patient had been ill for three weeks and was admitted gravely ill, with bloody diarrhoea, distension of the belly, a blood pressure of 90/75, dehydration, and a urinary chloride level of 1 g per litre. Trophozoites were found in the stools. He was given 5.5 litres of normal saline intravenously in 3 hours and rallied. Next day he was well hydrated, but he suddenly grew worse and died. Necropsy showed a friable congested large bowel with almost continuous white exudate and sloughs from cecum to rectum. No perforations were found.

EUROPEAN CASES

A European business man of 42 gave a fortnight's history of bloody diarrhoea. Sigmoidoscopy showed many superficial ulcers covered with exudate containing great numbers of amœbæ. All ulcers were healed on the 6th day of aureomycin treatment. On the 3rd day giant amœbæ were seen and from the 5th day onwards no amœbæ could be obtained from bowel scrapings. After 6 weeks he wrote that he was well, but his stools have not yet been re-examined.

A European child of 11 complained only of lassitude and headaches. Trophozoites were found in her stools. Sigmoidoscopy was normal. On aureomycin, amœbæ disappeared from the stools on the 5th day. Follow up with zinc sulphate flotation technique was negative 2 months later. Her symptoms were relieved within 2 weeks.

Two other patients, one a baby of 10 months, were successfully cleared of trophozoites, and follow up at one month was negative. Unfortunately we have no information on the effects of the drug in cyst passers.

COMPARISON OF AUREOMYCIN AND OTHER FORMS OF TREATMENT

For 4 years this unit has been engaged in therapeutic trials, the results of which have been published in three papers and in a letter to THE LANCET (Armstrong et al 1949, 1950). Some of these results are reproduced in

TABLE II—EXPERIMENTAL THERAPY OF ACUTE AMOEBIC DYSENTERY ASSESSMENTS AT 20 DAYS

Series	Therapy	No	Success (%)	Probable failure (%)	Absolute failure (%)	Removed from therapy (%)
A	Emetine gr 15 alone	50	50	32	28	—
B	Diiodoquin alone	50	58	18	24	—
C	Emetine gr 15 and diiodoquin	61	74	24	2	—
G	Diiodoquin and emetine bismuth iodide	50	80	14	6	—
I	Penicillin and sulphasuxidine followed by emetine and diiodoquin	56	95	5	0	—
J	Penicillin, sulphasuxidine, emetine and diiodoquin simultaneously	49	90	8	2	—
K	Sulphasuxidine, emetine and diiodoquin	49	88	10	2	—
L	Penicillin and sulphasuxidine	11	82	18	0	—
P	Sulphasuxidine alone for 20 days	57	54	12	7	27
Q	Penicillin alone for 20 days	55	46	16	16	22
S	Phthalylsulphacetamide alone	12	17	12	66	—
T	Carbarsone alone	50	48	10	6	36
U	Emetine bismuth iodide alone	55	71	9	2	24
V	Aureomycin alone	50	94	4	2	—

Once we had established a reasonably satisfactory form of therapy it was felt that we could no longer risk the lives of those whose condition was deteriorating with the form of therapy under trial and where this occurred patients were removed from treatment and placed on one or other of the forms of therapy which we knew were effective. These figures are shown in the last column. Naturally the earlier forms of therapy show no cases in this category because no better treatment was available.

table II for purposes of comparison with those of aureomycin. In all these previous series the criteria of diagnosis and selection were strictly comparable to those of the present series.

As a 27 day assessment was not made in all the previous series, our standard of immediate cure for comparison of aureomycin with other drugs has been taken at 20 days. It can be seen that aureomycin has been much the most successful single therapeutic agent, and the results of treatment with the standard amoebicidal drugs fall far short of it. The only comparable effects were obtained with a combined treatment of penicillin, succinyl sulphathiazole, emetine, and diiodoquin.

Our results show that aureomycin, when used alone, is capable of producing a very high cure rate at 20 days. In addition by the 9th day of treatment, 98% of the patients had been cleared of amoebæ. It is interesting to compare the success rate and absolute failure rate of aureomycin with those for emetine. Successes with emetine are 50% and with aureomycin 94%. Absolute failures with emetine are 28% and with aureomycin 2%.

Comment has been made on the rapidity with which the ulcers healed. Though this is the first series in which we have watched the ulcers daily, we feel that the rapidity of healing with aureomycin is much greater than with any other drug we have used.

Our experience with our small number of "follow ups" has been a great disappointment, for 14% of our successful cases have relapsed in the first 4 weeks after discharge. Our impression is that the relapse rate is higher with aureomycin than with other drugs used in the past. Though these early returning cases are classed as relapses, it must be borne in mind that these patients may possibly be peculiarly liable to reinfection, by virtue of their disturbed bacterial flora. In the circumstances to which they return after leaving hospital, reinfection is extremely likely. Recrudescence, however, remains the most likely explanation.

Our use of aureomycin alone in this series has been, of course, an attempt at scientific experiment and adventure rather than an attempt at therapeutic recommendation. The high relapse rate clearly shows that aureomycin should not be used alone but should be combined with one of the hitherto accepted amoebicides.

We think that with aureomycin the dosage of emetine or emetine bismuth iodide could be drastically reduced, and, though we have as yet no evidence, we believe that association of diiodoquin with aureomycin would reduce the relapse rate satisfactorily. The great potency of aureomycin suggests its use as the drug of selection in acute ulcerative amoebiasis, and, though other agents must be used as well, its advent has brought closer the day of ambulant treatment for this disease.

SUMMARY AND CONCLUSIONS

Fifty two cases of acute ulcerative amoebic dysentery have been treated with aureomycin alone. In the great majority this drug quickly relieved symptoms, cleared the patient of amoebæ, and induced healing of ulcers.

Aureomycin effects immediate cure in a higher proportion of cases than does emetine or any other single drug, but the relapse rate in the first month after cessation of treatment is high.

Aureomycin should not be used alone but should be combined with some other known amoebicidal agent.

Our thanks are due to the Council for Scientific and Industrial Research and to the Natal Provincial Administration. This work could not have been undertaken without the generous gift by Lederle Laboratories Division, American Cyanamid Company, of the very large quantities of aureomycin used.

CLINICAL TRIAL OF XYLOCAINE IN LOCAL ANÆSTHESIA

D. M. CARNEGIE

M.B. Lond., D.A.

CHIEF ASSISTANT, DEPARTMENT OF ANÆSTHETICS, GUY'S HOSPITAL

A. J. H. HEWER

M.B. Lond., D.A.

CONSULTANT ANÆSTHETIST, MIDDLESEX HOSPITAL

At the invitation of the Faculty of Anæsthetists of the Royal College of Surgeons of England, we have carried out a clinical trial of the Swedish local analgesic 'Xylocaïne'. Trials in Sweden (Gordh 1949, Bremer et al. 1948) and in the United States (Dabbs and Southworth 1949) suggest that this drug has some advantages over other local analgesics now in use.

Xylocaïne, or *o*-diethylamino 2,6-dimethylacetanilide, was first synthesised in 1943 by Löfgren (1948) and Lundquist (1946) at the Organic Chemistry Institute of the University of Stockholm, but they did not publish their results until 1946. The drug is a member of a group of basic amides, and has the following structural formula.

It bears a superficial resemblance to procaine, which is *p*-aminobenzoylethylaminoethanol.

But xylocaine is not a *p* aminobenzoic ester, nor is it closely related chemically to any of the commonly used local analgesics

The pharmacology and toxicology of the drug have been fully investigated by Goldberg (1947, 1948), who showed that although in concentrations above 0.5% its absolute toxicity is greater than that of procaine, the relative toxicity of xylocaine is lower because of its greater potency

CLINICAL TRIAL

In cooperation with our surgical colleagues, we have used xylocaine as a local analgesic in 138 cases for the following procedures

<i>Surface analgesia</i>	Bronchoscopy Ophthalmic surgery
<i>Infiltration analgesia</i>	Ventriculography (of brain) Minor surgery in outpatients Varicose veins Reduction of fractures (infiltrating fracture sites) Thoracoplasty Abdominal field block
<i>Regional nerve blocks</i>	Mandibular Maxillary Stellate ganglion (diagnostic) Brachial plexus Elbow, wrist, and digital Intercostal Posterior splanchnic Lumbar sympathetic (diagnostic and therapeutic) Caudal Sciatic

1 Surface Analgesia—For bronchoscopies, 2% xylocaine with 1/80,000 adrenaline produces analgesia which is fairly satisfactory but not so profound as that produced by 10% cocaine. This also applies to ophthalmic surgery, but we feel that 4% xylocaine would be more satisfactory. From observations of the eye after the application of 0.5% and 2% xylocaine without adrenaline, it appears that this analgesic does not either constrict or dilate the vessels, neither does it dilate the pupil nor produce mistiness of the cornea. As with cocaine, a very slight stinging sensation is sometimes felt when xylocaine is instilled into the conjunctival sac. The stinging is more pronounced when xylocaine is used with adrenaline. This is undoubtedly because the pH of 2% xylocaine by itself is 6.5, whereas that of 2% xylocaine with 1/80,000 adrenaline is 3.9, the pH of 5% cocaine solution being 5–5.5. (These pH readings have been determined by the "glass electrode" method on samples of the solutions we have used.)

2 Infiltration—In these cases, xylocaine with and without adrenaline has been used in concentrations ranging from 0.5 to 2%. For thoracoplasties, however, xylocaine has been shown to be effective in concentrations as low as 0.25% with 1/400,000 adrenaline.

3 Nerve blocks—For most of these, concentrations of xylocaine between 1% and 2% were used with 1/250,000 adrenaline. For caudal block, a 1% solution with adrenaline sufficed, and this had the advantage over procaine that the onset of the analgesia was two to three times as rapid, the effect lasted about 3 hours. In one case, a man of 73 had difficulty in micturition post-operatively, but in due course, after catheterisation, normal function returned.

In digital ring blocks, where adrenaline cannot be used, 2% xylocaine has the advantage that its effect lasts at least twice as long as that of procaine.

In therapeutic, and diagnostic nerve-blocks the long duration of action of xylocaine is particularly valuable, and for this purpose 2% xylocaine with adrenaline was used.

RESULTS

It was not possible to obtain numerical results in these cases, and for this reason we performed further investigations which are detailed later, but even from this first series certain points do emerge.

Xylocaine produces satisfactory analgesia, and in every case in which it was used without a general anæsthetic the sensory block outlasted the operation. With nerve blocks it was observed that xylocaine abolished tactile as well as pain transmission.

The motor paralysis produced by xylocaine is much more complete than that produced by other local analgesics. This is not always an advantage clinically but it suggests that the drug can more effectively penetrate nerves with thick medullary sheaths.

In a few abdominal cases which had an intercostal block accompanied by very light general anæsthesia we were disappointed because the motor block apparently wore off after about 2½ hours. This has been seen before with 'Nupercaine' and adrenaline mixtures, and the fault was believed to be not in the block but in the general anæsthetic, which had been allowed to become very light indeed, the administration of 0.1–0.2 g of thiopentone intravenously caused an immediate return of the relaxation.

With infiltration techniques, the area of analgesia obtained was markedly wider than the area infiltrated. This feature of xylocaine, combined with its high penetrating power, makes it valuable for any nerve block where accurate placing of the point of the needle is difficult.

Side effects

Unwanted side-effects were rare in our series, 1.4 g of xylocaine with adrenaline being the largest dose injected at any one time. One patient vomited after 0.8 g of xylocaine with adrenaline had been injected. Transient drowsiness and tremor have been noted, but these have not been severe enough to give rise to alarm, the slight tachycardia sometimes produced has been no greater than with other local analgesics mixed with similar quantities of adrenaline.

Small falls in blood-pressure (10–20 mm Hg) have been noted after infiltration analgesia, and greater falls (systolic down to 50–60 mm Hg) after posterior splanchnic with posterior intercostal block. In this latter group the fall is of course due to sympathetic block, and the pressure can be quickly restored with 'Methedrine' or some similar vasopressor drug.

No tissue irritation, either immediate or late, has been noted after an injection of xylocaine, and after the analgesia has worn off there seems to be even less tenderness at the injection site than there is with procaine.

SUBCUTANEOUS SKIN TESTS

To obtain accurate and more comparable results than were possible with the above techniques, we carried out a series of tests with various local analgesic solutions in normal volunteers.

Each subject received up to 6 injections of 1 ml. subcutaneously in various parts of the forearms, and the time of onset, duration, and spread of analgesia were investigated by response to pin prick. The end-point was taken as the time when complete analgesia disappeared, although it was noted that the original area of analgesia started to diminish in size about half an hour before it entirely disappeared. The character of the analgesia and its after effects could also be noted. Some of the results obtained were as follows.

EXPERIMENT 1 (16 VOLUNTEERS)

Analgesic solution	Average duration of analgesia
Xylocaine 0.5%	3 hr.
2.0%	2 hr.
0.5% with adrenaline 1/200,000	64 min.
2.0%	48 min.
	45 min.

EXPERIMENT 2 (8 VOLUNTEERS)

Xylocaine 2%	1 hr	35 min
Supercaine 0.1%		44 min
Procaine 2%		47 min
Xylocaine 2% with adrenaline 1/200 000	6 hr	54 min
Supercaine 0.1%	4 hr	42 min
Procaine 2%	4 hr	53 min

EXPERIMENT 3 (7 VOLUNTEERS)

Xylocaine 0.5% with adrenaline 1/100 000	5 hr	1 min
0.5% ' 1/250 000	1 hr	23 min
0.5% ' 1/500 000	3 hr	13 min

* From these results it appears that 0.5% xylocaine acts longer than 2% but the difference of 6 minutes is well within the limits of the experimental error and is not significant

From these tests the following additional conclusions can be drawn

(1) The onset of analgesia is more rapid with xylocaine than with procaine this was less evident with skin tests than with nerve blocks but in every volunteer the analgesia had come on before there was time to test with pin prick

(2) The spread of the area of analgesia is wider with xylocaine than with procaine, each being given without adrenaline

(3) The duration of action is much longer with xylocaine than with procaine and longer with xylocaine and adrenaline than with procaine and adrenaline of the same concentration (experiment 2)

(4) The effect of 0.5% xylocaine lasts as long as that of 2% without adrenaline, and when adrenaline is added to each, the ratio of duration with 2% xylocaine to duration with 0.5% xylocaine is only about 8/7 (experiment 1)

(5) The critical dilution of adrenaline appears to be in the region of 1/250,000 (experiment 3)

(6) Xylocaine appears to be relatively non irritant to the tissues, since no pain developed either on injection or on return of sensation. In 2 cases out of 26, however, there was slight tenderness on palpation, probably due to the formation of a hematoma

It is realised that these subcutaneous tests do not necessarily conform to clinical conditions. In deep infiltrations into more vascular areas, for example, the duration of action is shorter because the substance is carried away by the circulation. The tests do serve, however, as a basis for a comparative study.

The findings suggest that xylocaine compares favourably with most analgesics in common use, and in our view this substance merits further investigation.

SUMMARY

Xylocaine has been used as a local anaesthetic in 138 cases. It is a relatively non irritant analgesic substance of low relative toxicity with rapid onset and prolonged duration of action. In a concentration of 0.5% with adrenaline it produces almost as long an analgesia as 2% solutions. Tretile as well as pain sense is lost. It can be used for topical as well as infiltration analgesia. In the eye it produces no dilatation of the pupil or mistiness of the cornea. Adrenaline 1 in 250 000 is more suitable than 1 in 100,000. The dosage is the same as for procaine with a maximum of 1.0 g., although as a rule lower concentrations of xylocaine are satisfactory.

We wish to thank the Faculty of Anaesthetists for the opportunity to carry out this trial also the Astra Laboratories, of Södertälje, Sweden, Messrs C Tennant Sons & Co and Messrs Duncan Flockhart & Co for their generous supplies of xylocaine and last but by no means least our colleagues and volunteers for their help and co-operation.

BACTERIOLOGY REGISTRAR

BERNHARD BARON MEMORIAL RESEARCH LABORATORIES,
 QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON

The transmission of immunity from mother to child has been the subject of a great deal of experimental work in animals but little in man. And because of the anatomical differences the studies on lower animals cannot safely be used as a basis for conclusions on human transmission.

The work of Barr and her colleagues (1949, 1950) on the transmission of diphtheria antitoxin from mother to child has produced valuable and interesting results, some features of which are difficult to explain, in particular, they found a higher level of diphtheria antitoxin in cord blood than in maternal blood during

Fig 1—Relation between antistaphylococcal haemolysin levels in maternal and cord blood in 56 cases. Solid circles denote cases in which the antitoxin level was higher in the infant's peripheral blood than in the mother's. Arrows indicate the direction in which the points would have moved had an end-point been reached in those particular cases.

Fig 2—Relation between antistaphylococcal haemolysin levels in maternal and infant's peripheral blood in 51 cases.

delivery. It was thought that the transmission of staphylococcal antitoxin should also be studied, to see if the results were comparable. An investigation was therefore undertaken to compare the amounts of staphylococcal antitoxin (anti-haemolysin) in blood samples obtained from the mother during delivery, from the umbilical cord, and from the newborn baby, the object being to establish how far staphylococcal antitoxin, likely to be present in the mother, is transmitted to the baby, and in what amounts.

TECHNIQUE OF INVESTIGATION

In 56 cases samples of clotted blood were obtained from a vein of the mother during labour, from the placental end of the out umbilical cord before delivery of the placenta, and from the baby, by heel prick, within 24 hours of its birth. Some trouble was experienced initially in obtaining enough blood to provide sufficient serum for a complete titration. In a few of the earlier cases, therefore, no end point was determined, but nevertheless in most of these instances the result is conclusive.

The materials used in estimating the antitoxin levels were

Standard Staphylococcal Toxin (0.033 ml = 1 unit).—Standard toxin was diluted for the tests by adding 0.66 ml of toxin to 20 ml of borate buffer so that 1 ml contained 1 unit of toxin. A series of dilutions was then made from this solution as follows: 1/3, 1/2, 1/1.75, 1/1.5, 1/1.25 and 1/1. For the control tests the standard toxin was diluted 1/100.

Standard Staphylococcal Antitoxin (400 units per ml).—Standard antitoxin was diluted 1/3300 for the control tests.

Borate Buffer.—All dilutions were made in a buffer solution containing 5.7 g of borax, 8.4 g of boric acid, and 9.9 g of sodium chloride, made up to 1.6 litres with distilled water.

Tubes used for Tests.—For maternal and cord blood, 2 in by 1/8 in, and for infant's blood 2 in. by 1/4 in.

Sera to be tested were inactivated by heating for 1 hour at 56°C.

Test Cells.—5% suspension of washed rabbit red-cells in physiological saline.

Method

In a row of six tubes were mixed equal volumes of undiluted serum and the dilutions of toxin described

above. The tests stood at room temperature for 30 minutes. A double volume of test cells was then added to each tube, and the tubes were placed in the water bath at 37°C for an hour, left at room temperature overnight, and examined next morning. The end point was taken as the last tube in which no haemolysis had occurred.

The toxin control set up with each batch of tests consisted of six tubes, each containing 0.38 ml. of diluted toxin (1/100) to which were added the following volumes of antitoxin (1/3300): 1.1, 1.0, 0.92, 0.82, 0.75, and 0.5 ml. From this point the control tubes were treated and read in the same way as those in the test.

Separate pipettes were used for all the reagents throughout, they were cleaned by rinsing in distilled water, and dried in the electric oven.

RESULTS

In table I are presented the antitoxin levels of maternal blood, cord blood, and baby's blood. The differences and percentage differences between antitoxin levels of the maternal and cord bloods are also shown, the percentage difference being expressed in terms of the maternal blood level. In most cases the cord bloods and infants' bloods gave higher values than their respective maternal bloods. This is shown graphically in figs 1 and 2.

The findings are summarised in table II. The results omitted from this table are those in which the end point

TABLE II—SUMMARY OF FINDINGS

	No of cases	No of cases where antitoxin level was		
		Lower than maternal	Same as maternal	Higher than maternal
Cord blood (omitting* nos 11 and 13)	54	7 (13%)	7 (13%)	40 (74%)
Infant's blood (omitting* nos 2, 10, 11, 13, 25, 29, and 9, 18, 19, 20)	46	1 (2.2%)	3 (6.5%)	42 (91.3%)

* Not tested, or result inconclusive.

was inconclusive or no test was done, results which were conclusive although no end-point was found are included.

Taking the average of the percentage differences shown in table I, the antitoxin level in the cord blood was 63% above that in the mother. Considering individual cases, the antitoxin level was at least 50% higher in the cord blood than in the mother's blood in 31 instances, and in 18 of these the difference was 100% or more.

DISCUSSION

The transfer of tetanus immunity from mother to child was proved by Debré et al (1930), who showed that the antitoxin was present in the cord blood and infants of immunised mothers. From their description of only a few cases it is difficult to form an idea of the respective levels of antitoxin in mother and child. In 1932, however, Bryce and Burnet observed that the cord-blood level of staphylococcal hæmolyisin was sometimes as much as 100% higher than the maternal level, though at that time they did not appear to attach much significance to these findings.

Working with diphtheria antitoxin, Liebling et al (1941) demonstrated the presence of antitoxin in cord blood. In their cases the relation between the antitoxin levels in the cord blood and in the maternal blood was variable. Though they concluded that in most cases the infant's level equals that of the mother's, they presented 16 cases in which high maternal levels were attained, and of these the cord level was higher than the mother's in 9 cases and equal to it in 5.

These findings are interesting in view of the work already cited of Barr et al (1949), who, in their study of diphtheria antitoxin levels in 100 infants, reported that the antitoxin level was higher in the cord than in the maternal blood in 10 out of the 11 cases where both were tested.

Our investigation has demonstrated clearly that staphylococcal antitoxin is transmitted from mother to child before birth, and that there is a relationship between the mother's and the infant's antibody level. Further, it seems that in most cases the blood of the infant and cord is richer in antibody than the mother's. On the average we found the antitoxin level of the cord blood was 63% higher than that of the maternal blood. If this proves true of other antibody systems, the results may be related to the unusually high level of gamma globulins reported by Longworth et al (1945) in cord serum.

It seems that any adequate theory of the mechanism of transference of antibodies from mother to foetus must be able to explain the greater concentration of antibody in the foetal circulation. According to Brambell et al (1948, 1949) the only anatomical route available in the human is via the allantochorionic placenta. They showed that antibodies do not pass through the rabbit placenta in spite of the fact that the anatomical barrier in this animal is minimal. This view is contrary to that attributed by Liebling and Schmitz (1943) to Grosser (1909) in his extensive anatomical description of placenta. However, on reading Grosser's book we can find no experimental observations on the transmission of antibodies.

It is perhaps unwise at this point to speculate too deeply on the mechanism of transmission of antibodies, but it seems possible that the antitoxin molecule is so large that it may be unable to cross the placental barrier intact. Further experiments, with other antigen systems have therefore been initiated which it is hoped will clarify this problem.

SUMMARY

In 56 deliveries the concentration of staphylococcal anti-hæmolyisin was estimated in blood samples taken from the mother during labour, from the cut umbilical

cord before expulsion of the placenta, and from the infant in the first day of life.

The antitoxin levels were found to be higher in the cord blood and infant's blood than in the mother's blood in the great majority of cases.

Theories of the transmission of antibodies from mother to foetus must be capable of explaining this finding.

It is a pleasure to thank Miss Mollie Barr, MSc, and Mr A T Glenny, FRS, without whose advice on technique, and help in providing standardised toxin and antitoxin, the work could not have been done. We are also much indebted to Dr H J Parish and Dr C L Oakley for their valuable information and assistance. The material for this investigation was obtained through the co-operation of the obstetricians and paediatricians and also the labour ward staff of Queen Charlotte's Maternity Hospital.

Preliminary Communication

RAPID DETERMINATION OF BLOOD-SUGAR

A SIMPLE METHOD

WHEN a dilute solution of glucose is heated in the presence of sulphuric acid, a pink colour develops, the intensity of which is proportional to the concentration of glucose¹. On this fact is based a simple method for the accurate and rapid determination of blood sugar, depending not on the reducing property of glucose, as in other methods, but on the dehydration of glucose with the subsequent formation of hydroxymethylfurfural.

Reagents

- (1) Trichloro acetic acid (chemically pure) 5 g. Silver sulphate (analytically pure) 100 mg. Distilled water to make 100 ml. Store in an amber bottle.
- (2) Sulphuric acid (chemically pure), sp gr 1.840. Store in a stoppered bottle.

Procedure

- (1) Pipette 0.10 ml of blood into 1.90 ml of reagent 1 and mix.
- (2) Filter through Whatman no. 1 filter paper, or centrifuge.
- (3) Add exactly 1 ml of the filtrate to exactly 3 ml of reagent 2 in a wide test tube—e.g., 19 mm × 160 mm—and mix immediately by vigorous shaking.
- (4) Heat the mixture in boiling water for exactly 0.1/2 minutes, then cool in tap water.
- (5) Determine the optical density spectrophotometrically at 515 mμ and read the blood sugar level of the sample from a standard curve.

Determinations of blood sugar levels in a large number of samples both with this procedure and that of Somogyi² gave results which agreed very closely. The new method is accurate and simple, and requires only two reagents, which are stable for a long time and can be easily prepared or obtained. However, to avoid charring of extraneous material by sulphuric acid, the glassware must be kept meticulously clean.

One determination of the blood sugar level can be done by an analyst without special training in about

¹ Mendel B, Bauch M. *Klin Wschr* 1926 5 1329.
² Somogyi, M. *J Biol Chem* 1915 160 69.

10 minutes; since at least 20 determinations can be done by one person in an hour with a minimum of effort, this method seems to be particularly suited for use in clinical laboratories.

In cases where accuracy is not the first requirement but where speed is most important, the determination of the colour intensity can be further simplified by using a colour scale instead of the spectrophotometer.

Reviews of Books

Modern Trends in Orthopaedics

Editor SIR HARRY PLATT, M.D. M.S., F.R.C.S., professor of orthopaedic surgery University of Manchester
London Butterworth 1950 Pp 497 45s

Sir Harry Platt has collected together the contributions of 13 orthopaedic surgeons in this country dealing with subjects in which they have a particular interest and experience. Their views on the present status of the pathology and treatment of the conditions of which they write, and their survey of the evolutionary trends in management of major orthopaedic conditions, are of great authority. All the essays are good, and some are very good. Some stimulating thinking on paper about fracture problems comes from John Charnley. G. R. Girdlestone reminds us of the basic importance of sound conservative management in surgical tuberculosis, even in face of attractive new operations and chemotherapy, and has a valuable section on the operative treatment of Pott's paraplegia. V. H. Ellis deals with prostatic infections of bones and joints, but is perhaps not sufficiently clear on the indications for operation in acute osteomyelitis. Roelyn Jones combines the history of congenital dislocation of the hip with a proper emphasis on present-day treatment by gradual abduction, but he does not deal with the problem of anteversion of the femoral neck and its surgical correction, nor does he make the fundamental distinction of Levent between subluxation and dislocation as separate entities. Brian McFarland deals with congenital deformities in a typically individual way, but is a little sketchy on talipes equinovarus, not mentioning the Denis Browne method in any detail and perhaps unfortunately giving the impression that the tempo of correction need not be too rapid in the early weeks. Norman Capener and Roland Barnes have sound reviews of chronic arthritis and tumours of bone, and from Osmond-Clarke on scoliosis, Forrester-Brown on paralysis, and Lloyd Griffiths on vascular lesions, the reader gets the particular pleasure communicated by those who know and are in love with their subjects. There is also a very full and useful account of spinal injuries by A. N. Birkett, and Jackson Burrows ends the volume with a lucid catalogue of the bone dystrophies accompanied by a valuable bibliography. The book is a testimonial of the best standards of British orthopaedic surgery today, and (apart from some rather obscure radiograms) is beautifully produced.

Regional Ileitis

BURRILL B. CROHN, M.D. consulting gastroenterologist, Mount Sinai Hospital, New York. London Staples Press, 1949 Pp 229 30s

A MONOGRAPH on regional ileitis is timely, and this one is masterly. Since Dr Crohn and his colleagues described it in 1932, knowledge of the varieties and variations of this disease has greatly extended, and he now surveys the published work and relates it to his experience of 298 cases. No new light is thrown on aetiology, but the relation of the disease to tuberculosis and sarcoidosis is fully discussed, and a familial incidence and the possibility of a genetic factor are recognised. Morbid histology is based largely on the well-known work of Hadfield, published in 1939. Dr Crohn divides his 298 cases into four groups: regional ileitis, the ordinary chronic form, 222 cases; acute ileitis, 16 cases; ileo-jejunitis, 38 cases; and combined cases of ileitis with

involvement of some section of the large bowel (ileocolitis), 22 cases. Each group with its special manifestations is discussed in a separate chapter. X-ray diagnosis is illustrated by many good films and diagrams. He emphasises the importance of being ready to make a diagnosis on clinical grounds and act upon it, even when X-ray confirmation is lacking. Acute ileitis is regarded as an individual phase of regional ileitis, clearing up in 25-50% of cases, and advancing to the chronic form in the rest. The treatment of the chronic form is essentially surgical, and he favours ileocolostomy, with exclusion rather than resection. In laparotomy for acute ileitis he believes that the appendix should not be removed.

The chapters on the difficult combined forms—ileo-jejunitis and ileocolitis—and their differential diagnoses from the sprue syndrome and ulcerative colitis respectively, are a good summary of present knowledge. His view that ileitis and non-specific ulcerative colitis are if not identical at least of the same family, seems rather far-fetched and has little to support it in the text. There is a full list of references and no-one can grumble that British authors have not received their due.

Electrocardiography Fundamentals and Clinical Application

LOUIS WOLFF, M.D., consultant in cardiology, Beth Israel Hospital, Philadelphia and London. W. B. Saunders 1950 Pp 187 22s 6d

WITH the expansion of cardiology which has come through the use of new leads and the correlation of the results with the pathological findings, there is now a tendency to attempt a fuller understanding of the recorded patterns on the basis of electrical principles. This is the object of Dr Wolff's book, and the method of approach will be welcomed by most of those interested in the subject. The principles are clearly set out and are then applied to explain the patterns of bundle-branch block, hypertrophy, and cardiac infarction. Finally, records from patients with the various common types of myocardial disease are analysed according to the rules previously stated. The book succeeds more than most in giving a rational explanation for many of the abnormal patterns of the cardiogram, and if it sometimes fails to do so, this does not detract from the method employed, which only needs to be further pursued. The cardiologist should read this book, but the student will benefit by it only if he receives oral instruction on the same lines.

Paralysis Agitans

A Clinical and Genetic Study. HENRY MJÖNES, from the Psychiatric clinic of Karolinska Institutet, Stockholm. Copenhagen Munksgaard, 1949 Pp 195

WHEN it was first suggested, about 70 years ago, that heredity played some part in the aetiology of paralysis agitans, the demonstration of selected pedigrees showing a familial incidence of the disease was held to be sufficient proof of its hereditary nature. The development of both genetics and statistics since then, as well as the advances in medical diagnosis, have brought about great changes in attitude, and a good example of the modern approach to the problem is that of Henry Mjones in his recent investigation in Sweden. From the case-records of neurological, medical, and psychiatric clinics he located some 300 patients for whom the diagnosis of paralysis agitans or Parkinson's disease had been made. About a third of these cases were discarded after detailed examination, and his study is based on 194 probands with 162 secondary cases (not all of whom were available for examination) among their relatives. Clinically, he found considerable variability in the symptoms. Tremor was the most common and usually the initial symptom. The age of onset varied from 7 to 81 years, with a mean of 49 ± 14 years. Since all of the patients with age of onset less than 20 years belonged to families in which there were also cases with later age of onset, he thinks it unlikely that juvenile paralysis agitans is an independent entity. Nor could he find evidence of a special paralysis agitans psychosis. The only sex difference found was a slight excess of affected males among the parents of the probands and secondary cases, due perhaps to a lower probability of manifestation in females. The analysis of pedigree

was inconclusive or no test was done, results which were conclusive although no end point was found are included.

Taking the average of the percentage differences shown in table 1, the antitoxin level in the cord blood was 63% above that in the mother. Considering individual cases, the antitoxin level was at least 50% higher in the cord blood than in the mother's blood in 31 instances, and in 18 of these the difference was 100% or more.

DISCUSSION

The transfer of tetanus immunity from mother to child was proved by Debré et al (1930), who showed that the antitoxin was present in the cord blood and infants of immunised mothers. From their description of only a few cases it is difficult to form an idea of the respective levels of antitoxin in mother and child. In 1932, however, Bryce and Burnet observed that the cord blood level of staphylococcal haemolysin was sometimes as much as 100% higher than the maternal level, though at that time they did not appear to attach much significance to these findings.

Working with diphtheria antitoxin, Liebling et al (1941) demonstrated the presence of antitoxin in cord blood. In their cases the relation between the antitoxin levels in the cord blood and in the maternal blood was variable. Though they concluded that in most cases the infant's level equals that of the mother's, they presented 16 cases in which high maternal levels were attained, and of these the cord level was higher than the mother's in 9 cases and equal to it in 5.

These findings are interesting in view of the work already cited of Barr et al (1949), who, in their study of diphtheria antitoxin levels in 100 infants, reported that the antitoxin level was higher in the cord than in the maternal blood in 10 out of the 11 cases where both were tested.

Our investigation has demonstrated clearly that staphylococcal antitoxin is transmitted from mother to child before birth, and that there is a relationship between the mother's and the infant's antibody level. Further, it seems that in most cases the blood of the infant and cord is richer in antibody than the mother's. On the average we found the antitoxin level of the cord blood was 63% higher than that of the maternal blood. If this proves true of other antibody systems, the results may be related to the unusually high level of gamma globulins reported by Longworth et al (1945) in cord serum.

It seems that any adequate theory of the mechanism of transference of antibodies from mother to foetus must be able to explain the greater concentration of antibody in the foetal circulation. According to Brambell et al (1948, 1949) the only anatomical route available in the human is via the allantochorionic placenta. They showed that antibodies do not pass through the rabbit placenta in spite of the fact that the anatomical barrier in this animal is minimal. This view is contrary to that attributed by Liebling and Schmitz (1943) to Grosser (1909) in his extensive anatomical description of placenta. charts and determination of mendelian figures, together with an incidence of consanguineous marriages no higher than expected, indicate that the mode of inheritance is, in all probability, autosomal dominance. For those readers who wish to analyse the material for themselves, the case histories are given in tabular form in an appendix.

Das intrakranielle subdurale Hämatom

HUGO KRAYENBUHL, GAETANO G NOTO Berne
Huber 1949 Pp 175 Sw fr 18 50

THIS monograph from the neurosurgical clinic at Zurich sets out the clinical features, diagnosis, and treatment of subdural hæmatoma. It is based primarily on a survey of fifty cases of chronic subdural hæmatoma and three cases of acute subdural hæmatoma, which are presented in detail. A brief survey of the literature places rather much emphasis on subclassifications of types of "pachymeningitis." Perhaps the most useful sections are those on the various theories of pathogenesis and on diagnostic procedures. Unlike most other reports on this subject, this draws attention to the value of electroencephalography in the differential diagnosis. While neurosurgeons will discover few novelties here, and may perhaps find the case-histories rather tedious, it is nevertheless a useful survey of a subject that still awaits precise and comprehensive exposition.

Practice of Urology

HARRY C ROLNICK, M.D., professor of urology, Chicago Medical School Philadelphia and London J B Lippincott 1950 In two volumes Pp 1297 £9 9s the set

THIS is one of the most up-to-date and readable textbooks on the subject in the English language. Many of the excellent illustrations have already appeared in the popular treatise written by Professor Rolnick in conjunction with the late Dr D N Eisendrath, and those in the section on operative technique are well worth republishing. One could, however, wish for rather better cystoscopic plates. The work is singularly complete and mirrors well the modern American urological viewpoint. In addition it gives the ideas of the author, so that a balanced opinion can be formed of his practice—a feature which makes the book more useful to the younger specialist than a corresponding work by many authors. It is regrettable that little note has been taken of recent European advances, apart from Millin's developments in the field of retropubic surgery. We look in vain for any mention of the work of Denis Browne or McIndoe on hypospadias, of the Ombredanne technique in orchidopexy, of Wilson Hey's contribution to prostatic surgery, of the adaptation by Couvelaire of Marion's trocars technique for dealing with urethrovaginal fistulae, of the Hamilton Stewart operation for certain cases of hydronephrosis, or of recent British progress in the relief of stress incontinence of urine in women. As is common in American accounts, the names of foreign workers, when mentioned, are often incorrectly spelt—surely "Czerny" need not be "Cherney." Typographical errors abound, some not without humour: one figure, depicting varieties of bladder distension, has the caption "causes of pregnancy." Nevertheless, we can most heartily recommend this work, and only wish that the cost did not preclude its purchase by many of the younger surgeons.

Muskelpharmakologie

Und ihre Anwendung in der Therapie der Muskelkrankheiten OTTO RIESSE, professor of pharmacology, Frankfurt-on-Main Berne Huber 1950 Pp 232 Sw fr 16 80

THE contents of this book—which is to form part of *Lieferung VI* of Prof T Gordonoff's *Handbuch der Therapie*—are well described by its title, and Professor Riesser, who has been contributing to the subject since 1916, is well qualified to write it. He deals in the opening chapter with the physiological principles, histology, and physical and electrical phenomena of muscle, and in the main part of the book with the pharmacology of the skeletal muscles. This includes their stimulation by acetylcholine, the actions of

choline-esterase and its inhibitors—potassium, curare, guanidine, adrenaline, and other drugs. Short chapters follow on tone and the enzyme substrate relationships of myosine and adenosine triphosphate. A chapter on the metabolism of the muscle includes a very brief survey of the breakdown of carbohydrate. The last chapter is devoted to the therapeutic aspects, but there is curiously little about curare considering how much it has been discussed in recent Anglo-American literature, and this part of the book is not likely to be of great value to British readers. The bibliography is good but incomplete. Some 83 well-printed diagrams, mostly of drug-tracings, illustrate the pharmacological actions of the various drugs which are being described. The work as a whole is probably a worthy *Baustein* in Gordonoff's main edifice, but it is pre-war rather than post-war, and Continental rather than English, in approach. This may be a good thing, but the reader should be prepared for it.

Acute Appendicitis

FREDERICK FITZHERBERT BOYCE, M.D., assistant professor of clinical surgery, Tulane University of Louisiana School of Medicine New York and London Oxford University Press 1949 Pp 487 70s

THIS volume is recommended to anybody who wants to know what has been written about acute appendicitis. The author seems to have reviewed all the really significant articles, but it is not always easy to extract information from the book. For instance, the facts about conservative treatment have to be tracked down in three widely separated sections, and even then we are not quite sure of the author's personal views and experience. One strange omission is the method of proctocolysis. This excellent procedure for introducing fluid, which was ardently advocated by the great J B Murphy, seems to have been discarded by most American surgeons. It is good to see a small incision advocated (though the surgeon must be ready to enlarge it if necessary), but among the incisions mentioned we do not find the oblique incision straight through all the muscles in the right iliac fossa—one which has distinct advantages in certain circumstances. The instructions for dealing with an appendix abscess are extraordinary. The surgeon is told to examine the abdomen under the anaesthetic to determine the point of maximum fluctuation and to make the incision over it. Dr Boyce says that there is never any excuse for invading the peritoneal cavity in draining a fully localised appendiceal abscess walled off by adhesions, and the proposal is made that a sterile light should be introduced to make sure that all secondary loculations are opened up.

Apart from the practical side, there is much of interest in this book. The information is up to date, and the number of references is enormous.

Campbell's Operative Orthopaedics (2nd ed London, Henry Kimpton 1949 Pp 1643 2 vols £7 10s.)—This great orthopaedic textbook, appearing in its second edition after ten years, shows clearly that the experience and wisdom of the late W C Campbell have not been lost, but have been handed down to his editors, J S Speed and Hugh Smith, and their colleagues, to whom the revision must have been a labour of love. Much of the text remains unchanged, and only minor alterations in arrangement have been made, but many orthopaedic advances which were novel or experimental in the first volume have now become routine practice and considered opinions are given of their merits. While newer methods, such as cup arthroplasty, intramedullary nailing, trochanteric nailing and disc surgery, are well described by various writers. Though encyclopaedic in scope, the work is not in the main overloaded. The writer of the good chapters on amputations in a few words relegates to the junk room many of the obsolete operations so often slavishly described, but includes many other novel and ingenious amputations, either because they may be good in themselves or because they may stimulate further advances. A standard below knee and a standard above knee amputation, to which we in this country seem to be becoming regimented, do not seem to be gaining ground in America. Nearly all the original illustrations remain, supplemented by many new diagrams and X ray photographs.

produced by oxygen-enriched air, but unfortunately it is still impossible to estimate plasma oxygen levels directly—they can only be calculated. GRAHAM et al.⁵ think that the infants are mainly suffering from a defect in oxygen exchange from blood to tissues.

Providentially, newborn mammals can survive anoxia much longer than they can later, and the less mature they are at birth the longer their survival time. The two main reasons for this are their low cerebral metabolic rate and their faculty of anaerobic metabolism which is characteristic of foetal life and persists for a short time after birth. The foetus and newborn use less oxygen per unit of energy than older mammals do, because their metabolism has an end point in carbohydrate breakdown short of carbon dioxide and water.⁴ Nevertheless, those who suffer from prolonged anoxia may sustain permanent tissue damage if they survive. The central nervous system is the most vulnerable part of the body to anoxia, and its vital processes cannot withstand oxygen lack for longer than five or six minutes without harm. The mechanism of the pathological changes produced is a complex one, involving functional, metabolic, and structural factors, and capillary hæmorrhage may also become serious in some situations. A considerable proportion of cases of cerebral palsy, personality disorder, and mental defect are now thought to be sequelæ of foetal or neonatal anoxia. For the great majority, however, nature has provided adequate safeguards against this hazard of birth.

Trends in Tuberculosis

A GRAPH of the mortality from tuberculosis for the past century is agreeable to contemplate, so steady has been the decline, but does it give an accurate picture of what is going on? Dr HERBERT R. EDWARDS and Mr GODIAS J. DROLET⁷ think it time we turned our eyes from the cemeteries and premature graves and considered the living tuberculous, for, unless the incidence of new cases is also falling, we cannot regard the disease as under control. They say that between 1940 and 1947, though the tuberculosis death-rate in the United States fell from 45.8 to 33.5 per 100,000 population, the number of new cases registered (the morbidity-rate) rose from 76.4 to 93.3 per 100,000. Some of this rise is of course due to better ascertainment—especially of early cases—by mass radiography, but it cannot all be explained in this way. Thus in New York in 1947 mass radiography accounted for only 3.4% of the new cases registered, whereas 86% were in the second or third stage and diagnosed by other methods. In Los Angeles in 1948 nearly 87% of cases were already "advanced" when notified.⁸ Admittedly the morbidity-rate is no direct measure of the amount of tuberculosis in a community, for tuberculosis is a long disease, and the yearly increment of new cases merely swells an existing tuberculous population of uncertain dimensions. But the fact that the morbidity rate is rising suggests that this population may be growing, despite the benefits of modern treatment.

In our own-country the picture is similar though

not identical. In England and Wales, the death-rate from pulmonary tuberculosis fell from 56 per 100,000 population in 1940 to 44 in 1948, but the morbidity-rate rose from 111 to 121. Actually the notification-rate is not a very satisfactory figure to go by, because not all the cases notified prove to have the disease, but we also know that the number of cases on the dispensary registers has risen almost steadily, from 188,752 in 1939 to 271,552 in 1949. (These totals may be swollen by some recovered cases whose names have accidentally been left on the registers, but *relatively* they are comparable, and a rise of over 80,000 can hardly be without significance). During the past eight or ten years, then, here as in America, the mortality-rate has been declining but the incidence of new infections apparently has not. In both countries the cases under treatment have increased, the sanatorium waiting lists are lengthening, poor housing and overcrowding are helping the spread of infection, and the pool of active cases in the community is almost certainly growing larger. The falling death-rate may, in fact, be misleading, for, though it must depend partly on modern methods of treatment, it also partly is a legacy from the days, 15 or 20 years ago, when beds and nurses were better matched to the number of patients, and when on the whole there was probably less overcrowding of houses. In another 15 and 20 years' time we may possibly pay with a rising death-rate for our present failure to control infection.

To cope with the new cases clinics are working harder than ever before. In New York, field visits paid by health department nurses to patients or their families in their homes fell by a third between 1945 and 1948, largely because the clinic staffs were so busy that less time could be spared for visiting. The New York Tuberculosis Association comment that "it is impossible to avoid thinking of a possible link between this reduced amount of home supervision and the spread and increase of tuberculosis in New York City in the past few years." The load on our own clinics is hard to estimate accurately. Their number has not increased greatly to meet the growing demands on them: there were 471 in England in 1938, and 492 in 1947. Graphs made at a typical clinic show that, between 1939 and 1949, the number of patients systematically examined by the physician nearly doubled, and so did the total attendances, while X-ray examinations became more than six times as numerous, and refill attendances of patients with artificial pneumothorax rose from 877 to 3024. The clinics in fact are doing a great deal of work which was formerly done by the sanatoria, and their routine work will become even heavier if BCG is used on a wide scale. All this means that there is less opportunity for home visiting or follow up.

Weaknesses in our tuberculosis scheme have always been evident. In the days before the war, standards in different areas varied with the keenness of the local authorities and the amount of money at their disposal. In some areas the care offered was first-rate, in others it was very poor. The National Health Service Act, by reducing financial differences, has removed some of this inequality, but it has not, of course, been able to create staff, conjure up new hospital buildings, or solve the country's housing

⁸ Tuberculosis Reference Statistical Year Book 1948 New York Tuberculosis and Health Association 1949

of oxygen utilisation with exceptional reduction of oxyhaemoglobin, and the increased placental blood-flow. In the human foetus conditions are similar, and various adverse circumstances may precipitate a serious oxygen want. BARCROFT¹ divided anoxia into anoxic, anæmic, and stagnant types, according to whether the defect lies in the oxygenation, oxygen transporting mechanism, or capillary circulation of the blood. Foetal anoxia is almost invariably of the anoxic type and usually originates outside the body of the foetus. The two main causes are reduction in the oxygen tension of the maternal blood and interference with the passage of oxygen from mother to foetus. The mother's oxygen tension may be reduced by asphyxiating anaesthetics, notably nitrous oxide, by any factors that lower her blood pressure, such as spinal and caudal anaesthesia, or by systemic diseases such as the anæmias, heart-failure, and pneumonia. The transfer of oxygen from mother to foetus may be interrupted by the tetanic uterine contractions which pituitary extract sometimes produces, by separation or infarction of the placenta, or by prolapse or knotting of the umbilical cord.

The laudable quest for painless childbirth has increased the incidence of serious foetal and neonatal anoxia, since all the known analgesic, sedative, and general anaesthetic drugs, if given to the mother, will affect the central nervous system of the foetus. EASTMAN,² a leading authority on foetal anoxia, showed that gas and-oxygen containing not more than 85% of nitrous oxide can be administered to the mother for periods of under three minutes without endangering the foetus, but that giving a mixture containing over 90% of nitrous oxide for longer than three minutes will cause severe foetal anoxia in a third of the cases. The neonatal apnoea associated with nitrous oxide is an anoxic rather than a narcotic effect. When ether is given in childbirth it does not cause any anoxia, but its narcotic action often delays the onset of the infant's respiration as long as the anoxia of nitrous oxide. Before delivery the concentration of ether is similar on the two sides of the placental membrane, but thanks to the high volatility of ether it is rapidly excreted by the infant's lungs, more than half being eliminated from the circulation within three minutes of birth. In the last decade cyclopropane has been increasingly used in obstetrics for maintaining anaesthesia after thiopentone induction, it is usually given in a concentration of 5% with 95% oxygen, and thus will not significantly depress the oxygen tension of either the maternal or foetal blood. However, like ether, cyclopropane diffuses readily through the placenta and it has the same potentiality for narcotising the foetus. LUND³ takes the view that it is therefore not completely safe for the foetus. Curare, which is often given with cyclopropane to ensure good muscular relaxation, apparently does not pass the placenta, for it does not affect the neuromuscular end plates of the foetus. Trichlorethylene is now much used for self-administration by the mother during pains, it is a more effective analgesic than nitrous oxide, and intermittent administration precludes appreciable foetal damage

in either case. Thiopentone is the most popular intravenous anaesthetic in current obstetric practice. It acts very rapidly and is also rapidly transferred across the placenta. Induction should therefore be delayed until the last moment and the delivery performed as expeditiously as possible, even at some depression of the foetal respiratory centre is unavoidable. It is clear then that the ideal obstetrical analgesic has yet to be discovered, and, as LUND says, choice of drugs is less important than skill in using them.

The inception of pulmonary respiration at birth is a remarkable and dramatic event. Normally the sensitivity of the brain to respiratory stimuli is unimpaired by birth processes such as the transient anoxia associated with uterine contractions, and the many sensory stimuli that arise directly after birth start the baby breathing straight away at the controlled rhythmic level. But in cases of respiratory depression, whether from anoxia, narcotics, anaesthesia, haemorrhage, or oedema, respiration begins quite differently, in gasps. A gasp is a forced inspiration involving much of the musculature of the body, it is the most primitive respiratory movement, the first to appear in the developing foetus, and it has a purely medullary mechanism. The respiratory inhibitors, such as anoxia and anaesthetics, inhibit the brain centres from above downwards, and when only the medullary centres are functioning the gasp is the only possible respiratory response to any stimulus. After a pause the baby gives another gasp, followed by others, and so it gradually secures enough oxygen to bring into action the higher parts of the brain which will establish a respiratory rhythm. If the gasps do not achieve this result they diminish in frequency and intensity and the baby dies. The manner of onset of respiration is a valuable index of the state of the central nervous system, it should therefore be more closely observed and carefully recorded, for it may provide valuable evidence in the future, particularly in cases of cerebral palsy and mental defect. The alternating hyperpnoea and apnoea commonly seen in premature infants is a characteristic of "mountain sickness" and gives place to regular respirations in an oxygen enriched atmosphere.⁴ Premature infants with periodic respiration should therefore be given oxygen, though we do not yet know the exact mechanism of the periodicity or how the oxygen stimulates regular respiration. GRAHAM and colleagues⁵ found that the average arterial oxygen saturation in a group of premature infants was 93% in atmospheric air (adult controls 94%) and 100% when they were breathing 70-80% oxygen, thus, optimal function of the respiratory centre, as shown by regular breathing, was not attained until an oxygen enriched atmosphere forced the arterial saturation to almost 100% and presumably greatly increased the amount of oxygen dissolved in the plasma. In view of the essentially normal haemoglobin saturation in these premature infants, WILSON⁶ believes that physically dissolved oxygen must play a large part in the effect

health and health visitors—were not professional interviewers, but were trained in the subjects under investigation

It is important to realise the limitations of sample survey investigations. They are unlikely to explain etiology, and they can seldom achieve exact diagnosis. But they may yield new light on old problems, which can be followed up in the laboratory or clinic. Above all, they can tell us where and whether human needs are being met, and how the new galaxy of social services is operating at the receiving end. The sample survey should be the administrator's intelligence service, as essential to his operations as are the X ray film and the blood count to the surgeon's. As P. E. P. says, "Despite the rapid enlargement of the health services, no adequate machine has yet been set up to discover what return is being made for the skill and money expended. Many of the services are experimental, and there is need for a rapid and objective measure of their success. Such a measure could well be supplied by sample survey techniques."

THE LISTER INSTITUTE

RESEARCH WORKERS and clinicians have cause to be grateful for the solid, though often unobtrusive, achievements of the Lister Institute, and the latest annual report¹ shows that the volume of useful work is still as great as in former years. In the bacteriology division studies which are now in progress include one into the possible relation between "iso allergic encephalitis" and postexanthematous encephalitis, with special reference to postvaccinal encephalitis. Groups of guinea-pigs have been sensitised in various ways with emulsions of both heterologous and homologous cerebral white matter, with and without adjuvants. A few of these animals have developed paralytic symptoms, and the histology of their central nervous systems is being examined. After an interval to exclude the occurrence of further cases of paralysis due to the sensitisation alone these animals will be infected with vaccinia virus adapted to the guinea-pig and watched for the development of any abnormal symptoms. Another group of workers has been engaged in preparatory experiments for investigating the fate of dextran in the body after injection. An accurate method of determining dextran in rabbit urine has been worked out, and pilot experiments on the effect of controlled acetone fractionation and hydrolysis on the molecular size of dextran in relation to renal excretion have been performed. Similar experiments on the effect of dextran of different molecular sizes on the histological structure of various tissues are in progress. In the biochemistry division, the gene product responsible for the recently discovered human blood group "Lewis" has been obtained in essentially homogeneous condition. Last year it was reported that "Lewis" positive adults are "non secretors" within the ABO classification, but the observation that "Lewis" positive persons secrete a specific water soluble gene product shows that there are in fact no "non-secretors," all persons secreting one or more of their blood group factors in a water soluble form. It is now postulated that the "Lewis" genes and the genes of secretion probably belong to one genetical system.

The Medical Research Council's bacterial chemistry unit has now been transferred to the National Institute of Medical Research at Mill Hill, and the National Collection of Type Cultures to the Central Public Health Laboratory at Colindale. The blood products unit, the blood group research unit, and the blood group reference laboratory are still accommodated at the institute. The blood products unit has continued to produce dried human plasma and plasma fractions for the Ministry of

Health. Half of each batch of gamma globulin has been concentrated by drying from the frozen state in bulk, reconstituted in smaller volume, bottled to give 250 mg per ampoule, and held as a liquid. The other half has been ampouled before drying in the ordinary way, in quantities containing 250 mg. The relative potency of material prepared in these two ways is to be tested clinically by the Public Health Laboratory Service.

BONE METABOLISM

BEFORE the days of the microscope John Hunter predicted a mechanism for removal by absorbents of those portions of a bone which needed reshaping in the process of growth. The histological mechanism subsequently discovered was resorption of bone by osteoclasts, with apposition of new bone, first as a thin seam of osteoid tissue, by osteoblasts. Thus osteoclastic resorption and osteoblastic apposition goes on throughout life and corresponds in biochemistry to the calcium balance. Professor Albright¹ came into the story in 1925 when the parathyroid hormone was discovered. Working with J. C. Aub he was able to show that repeated injections of the parathyroid hormone in normal man raised the blood calcium and stimulated excessive osteoclastic resorption, throwing the patient into a negative calcium balance. There are still some who maintain that the bedside clinician cannot grasp enough elementary biochemistry to understand this, but like most true discoveries in science it is simple. What was laid down by Aub and his students in 1925 in the Massachusetts General Hospital led all over the world to the diagnosis, on the clinical, biochemical, and radiological evidence, of cases of hyperfunction of a parathyroid tumour—in other words hyperparathyroidism. Numerous sufferers from what had been an incurable skeletal disease, the generalised osteitis fibrosa of von Recklinghausen, were cured by surgeons who explored the neck and removed what they could not feel because it was tucked away behind the thyroid gland—a parathyroid tumour.

All this work threw emphasis upon another gross skeletal disease brought about by excessive osteoclastic resorption—namely multifocal osteitis fibrosa, known in the United States as polyostotic fibrous dysplasia of bones. In this disease there is no evidence of metabolic disorder, both the blood chemistry and the calcium balance are normal, and exploration of the neck for a parathyroid tumour is wholly unjustified. Careful radiological studies show that the bone shadows are normal in between the foci of disease, X rays, therefore, emphasise that the condition is not a generalised skeletal disease. Endocrine glands other than the parathyroids influence the state of calcification of the skeleton, for example, osteoporosis is often present in long-standing cases of hyperthyroidism, and osteoporosis chiefly affecting the spine is a characteristic feature of Cushing's syndrome. Albright's work adduces convincing evidence that the spinal osteoporosis of elderly women is also the result of an endocrine imbalance. There is a considerable body of experimental evidence that oestrogens influence bone formation. In female pigeons there is a considerable rise in the serum calcium level before ovulation, with reversion to normal after ovulation. Albright investigated the effect of oestradiol benzoate on the calcium and phosphorus metabolism in women suffering from postmenopausal osteoporosis. He demonstrated that this oestrogen promotes a considerable retention of calcium and phosphorus, through a reduction of both the faecal and urinary excretion.

problem. Moreover, as Dr F HALL puts it in the June issue of the *N A P T Bulletin*, it has produced "a state of administrative divorce between the curative and preventive branches of medicine." Dr W L BURGESS points out that the local health authority is handicapped in preventive work by the loss of the dispensaries, which now come under the hospital authorities. There is a danger that the dispensaries, formerly the very centres of preventive education and aftercare, may become purely clinical institutions or outpatient departments. Undoubtedly the service might gain much if advisory committees were established to integrate the tuberculosis work of each region. At present, as Dr F A H SIMMONDS says, we are "fighting with two armies who not only have no unified command, but have no joint plan for the common task." What has been gained on the hospital side (and thanks to advances in thoracic surgery, and the better deployment of thoracic surgeons, this has been much) is offset by a decline on the preventive side. Moreover, the economic position of patients, though in theory as good as it was before, now requires an unpopular appeal to the Assistance Board.

Some means of limiting the spread of infection more effectually are already being tried. Domiciliary treatment, used in conjunction with hospital care, has already enabled many patients to become sputum-negative—and therefore safe companions for their families—within a few weeks or months of diagnosis. But this does not mean that domiciliary care is the ideal treatment for every patient, or even for most, and it should be regarded mainly as an expedient capable of helping us through a difficult phase. A second measure now widely recognised as necessary is that the general and teaching hospitals should reserve a proportion of their beds for tuberculous cases. This could at one stroke provide beds for all early cases, and would have the additional advantage of making all student nurses and future doctors familiar with a widespread disease of which they are nowadays too often ignorant. The difficulty that some of the nurses in these hospitals may object to looking after patients diagnosed as tuberculous can be overcome—as Dr HORACE JOULES is showing at the Central Middlesex Hospital—when proper precautions are taken for the care of their health. In this hospital all patients in the general wards who are suspected of tuberculosis are transferred at once to a tuberculosis unit in a separate building, and only Mantoux positive nurses are allowed to look after them. The health of all the nurses is carefully supervised, and the incidence of tuberculosis among them is lower than in any of the hospitals studied in the Prophit investigation⁹ indeed Dr JOULES hopes to be able to show in a year or so that it is no higher than the incidence of tuberculosis in young women of the same age group in the general population. He warns all prospective students and their parents that they will be expected to nurse tuberculous patients, and he has never had a refusal. As the care of the nurses could perfectly well be of this standard in all hospitals, there seems to be no adequate reason why those who control our hospital resources should go on denying tuberculosis the larger share it so

clearly deserves. As a rule we are rightly anxious to treat quickly the patient whose life is threatened, even though the chances of cure may be small and the risk is to the patient alone. Yet we turn a curiously blind eye to the tuberculous, whose life may be threatened as gravely, whose chances of cure are often good, and whose infection, untreated, will spread and spread and spread.

Annotations

SAMPLE SURVEYS

THE sample survey as a tool in medicosocial research has come to stay, and P E P has done a thoroughly useful job in issuing two broadsheets¹ describing in fair detail the present position, both as to techniques and organisations in the field. The essence of the sample survey differs in no essential from the familiar technique of the blood count. In each, a tiny fraction only of the whole is examined, and from this deductions about the whole are made. In each, a measurement is made while the vast multitude to whom it applies, whether human or cellular, swirls by unaware that it has been measured. The process of sampling, though to the outsider the most fallible part of the job, is in fact the least chancy of all the stages; since, provided well authenticated rules are followed, the precise margin of error is known. The analysis of results, using the punched or clipped card technique, can also be rendered entirely automatic, though special precautions are necessary since the high speeds of work tend greatly to magnify human error.

The key to successful sample survey work lies in the design of the questionnaire and the conduct of the interview. A careful pilot inquiry, using the free interview method, is a usual first step in any new field of investigation, for nothing is harder than to judge, in vacuo as it were, what questions a sample of the public can or cannot answer. Inability to answer relates mainly to memory or lack of experience. For example, it is of little use to find out what people think of heating or lighting methods of which they have had no personal experience, or products which they have never tried. On the other hand, it seems that when faced with an investigator, questionnaire in hand, the large majority of people tell the truth. In most situations, the Law of Least Energy operates: that is to say, it is easier to speak the truth than to make up a lie. Where social prestige operates, this does not apply. For example, the question, "Do you go to church regularly?" invariably produces an inflated answer. To get at the true facts, all mention of church can be excluded from the questions, every alternative Sunday occupation is checked over, and then the crucial question is popped: "And did you do anything else?"

In the medicosocial field, the Government Social Survey, now a permanent institution, has been making history since 1945 with its monthly Health Index for the Registrar General. At present Britain is the only country in the world to collect a complete picture of national morbidity, though the United States intends shortly to follow our example. Ad hoc medicosocial sample surveys include such notable efforts as the maternity services investigation made by the Royal College of Obstetricians and Gynaecologists and the Population Investigation Committee. This was in fact a census of all women giving birth to children in a single week in March, 1946. Its success (13,687 women cooperating out of 15,130) was due to the efforts of nearly all the local health authorities in the country. The investigators—medical officers of

Total cost	£48,215	£64,370
Average cost of each outpatient attendance	6s 10d	8s 10d
Average cost of each outpatient	£1 16s 1d	£1 17s 6d
Analysis of cost of each outpatient		
Cost of outpatient department	£1 2s 4d	£1 6s 0d
Cost of special services	13s 9d	11s 6d
	£1 16s 1d	£1 17s 6d

appeared between April and September. Tables based on them were then compiled and published in the statistical summary of King Edward's Hospital Fund for London and the *Hospital Year Books* of the British Hospitals Association. It was thus possible for anyone interested in hospital economics to form some idea of the trend of hospital costs and of how hospital services were being used. The report of the Comptroller and Auditor General on the accounts of hospitals and executive councils for the first nine months of the health service has now been published.¹ But this does not give any analysis of the cost of individual hospitals, and in view of the increases in the estimates for the health

service it may be of interest to examine the cost accounts of one hospital, the Radcliffe Infirmary, Oxford, for the period July 5, 1948, to March 31, 1949, and to compare them with an almost similar period immediately preceding the appointed day—i.e., Oct 1, 1947, to July 4, 1948.

In 1937, three wards at the Radcliffe Infirmary were allocated for the use of the newly appointed Nuffield

professors of medicine, surgery, and obstetrics and gynaecology, and it was agreed that the cost of certain patients should be borne by the research funds of the Nuffield Committee for the Advancement of Medicine. To find out what these patients cost, a departmental costing system was instituted by which the total expenditure of the hospital was allocated to individual wards and to outpatients. Details are thus available of the cost of each ward and department of the hospital and of the services they render. The system has now been extended to cover the other hospitals within the United Oxford Hospitals group. A general increase in costs since July 5, 1948, is shown, but it should be pointed out that all known increases in salaries, including those of medical and dental staff under the N.H.S., are taken into account.

From table I it will be seen that, in the nine months after the National Health Service started, the number of new outpatients was 28.6% higher than in the previous nine months, while the corresponding rise in the number of attendances was only 2.7%. This could imply that increased efficiency in the department reduced the need for attendances. On the other hand, it might mean that a greater proportion of the patients were referred to the department for less acute conditions.

Figures are available which show the average weekly cost of inpatients in medical, surgical, ENT, maternity,

and private wards, and also in the research beds for neurosurgery, gynaecology, and medicine. Tables II and III show the costs in the medical and the surgical wards during the nine months before and after July 5, 1948.

As one would expect, the cost of a surgical bed is higher than that of a medical one, for it carries a greater share of the theatre costs.

The percentage increase is 45 for medical beds and 46 for surgical beds. The period is too short to allow of generalisation, but it is evident that if allowance is made for the increases in the salary scales of medical and hospital staff, the introduction of the health service did not cause a phenomenal rise in costs.

TABLE IV—ANALYSIS OF TREATMENT AND COST OF INPATIENTS

Cost per inpatient	£19 11s 9d	£30 1s 2d
Cost per inpatient week	£10 8s 3d	£15 12s 6d
Total expenditure	£181,361	£273,937

1 See *Lancet*, 1950, I, 681

Oestrogen therapy also lessened or eliminated the pain in the bones and produced general constitutional improvement. Albright concluded that bone formation is influenced by certain of the steroidal hormones. According to his hypothesis the steroidal hormones, promoting anabolism of protein, stimulate the osteoblasts, while the "sugar active" corticoids of the adrenal cortex, which inhibit protein anabolism, depress the activity of the osteoblasts. At the time of the menopause the laying down of organic matrix fails to keep pace with bone resorption and a reduction in bone substance results.

THE NUFFIELD FOUNDATION

THE Nuffield Foundation was brought into being for the purposes of promoting health, social well-being, and the care and comfort of the aged poor. The trustees might thus have diffused the funds over a vast field of constructive endeavour. Instead, they wisely chose to concentrate them where the need was keenest, and the report for the past year¹—the first of the Foundation's second quinquennium—shows that this policy remains unchanged. In curative medicine, substantial grants have been promised for investigations of the modes of action and methods of synthesising 'Cortisone' and allied substances and earlier projects in the fields of medicine (including social medicine), the natural sciences, and the social sciences are promised further support. In its second five years the Foundation is concentrating particularly on fundamental research, notably in biology and sociology. In biology new grants have been made for studies of the factor determining the difference between cell types, of various types of learning system, of the control of regional determination in embryos and of the migration of cells in embryos and in adult life, of X-ray analysis of crystals, and of tissue culture. In sociology grants are being made for investigations of the costs of founding and raising a family, of the patterns of family life, of the techniques of social surveys, and of the progress of 2000 Scottish 11 year olds, in the whole range of intelligence, who were first tested in 1947. By its fellowships and scholarships the Foundation has already done much to bring together teachers and others in the Commonwealth who might otherwise never have met, and it is now prepared to take a more direct hand in Commonwealth affairs by grants for research in overseas universities and similar institutions. (A Nuffield research professorship of mechanical engineering has already been endowed in New South Wales.) The Foundation now discharges its obligation to the aged through the National Corporation for the Care of Old People, but the report speaks pertinently of one aspect which is becoming more important.

"The increasing infirmity which often accompanies increasing age is a problem which every home for the able-bodied—whether run by local authorities or by a voluntary society—has to face eventually, for, however spry the residents may be when admitted, some of them will decline into progressive ill health and will need much more physical help and more continuous care than a lightly staffed home can easily provide. At present it is nearly always impossible to gain admittance for a case of this kind into hospital. Indeed there is a real danger that in a few years from now many of the homes recently established may degenerate wholesale into medical slums unless some simple and smooth transition can be effected to a stage half way between the two types of care provided respectively by the welfare and the health authorities."

Every project, says the report, is measured against its presumed or even its speculative, contribution to the practical betterment of life. Perhaps the Foundation's most notable achievement has been to further rational humanitarianism.

HUMAN PERFORMANCE

OWING partly to war-time research, we are particularly well placed to assess capacity for work and the causes of failing performance. During the late war Dr N. H. Mackworth conducted extensive studies of performance in a wide variety of tasks, and his findings, now published,¹ will be of interest far outside the confines of the psychological laboratory. Indeed he provides good evidence for the claim that "it has now become perfectly possible for experimental psychology to furnish assured and practical answers to questions concerning the limiting conditions under which even complex human operations can be maintained at a high level of accuracy with the minimum strain."

Dr Mackworth's studies, directed to the solution of problems arising in the extremely practical circumstances of armed conflict, owed much, as he points out, to the inventiveness and theoretical brilliance of K. J. W. Craik, whose influence on the present generation of experimental psychologists has been profound. His investigations fall into two main groups, concerned with (1) vigilance, and (2) the effects of environmental stress. In the work on vigilance the situations which, under Service conditions, had produced the problems were imitated closely in the laboratory. Two visual tasks were studied in connection with the difficulties found in 1943 in the routine use of radar, and auditory vigilance was studied in a third task simulating the operation of an 'Asdic' apparatus. In all three tasks significant deterioration, as measured by the number of signals missed, was found during a two hour watch, beginning before the end of the first half hour. This deterioration was related to the difficulty of the task and the competence of the operator, for it did not take place when the initial level of missed signals was low. It could be prevented for the full two hour period by methods which kept alive the operator's interest—for instance, interruption of the task by the experimenter, or supplying knowledge of results—or by amphetamine sulphate in 10 mg doses. Dr Mackworth interprets these findings in terms of Pavlovian conditioning. The researches on environmental stress deal with the effects of harassing gases and of high atmospheric temperatures. Measurements were again made in several types of performance analogous to those required in the Services. An interesting finding was that deterioration in intensive forms of work was related logarithmically to increase of temperature. Physiological indices proved unreliable, except when the physiological state directly responsible for the deterioration could be identified.

The experiments are clearly described and should be readily capable of repetition and extension. The techniques are of a kind which ought to be of equal value in dealing with the problems of peace time.

THE first two years of the National Health Service were reviewed by Sir Andrew Davidson, chief medical officer of the Department of Health for Scotland, when he addressed the Society of Radiographers at a dinner in Edinburgh on June 23. A proper balance must, he said, be struck between the various elements of the service "more and more attention, for example, will need to be paid to those working in the homes of the people." Then, the quality of the service must be maintained at the highest standard, though "how this is to be done is difficult to see." A further requirement was to encourage research, both laboratory and sociological. Finally the public must be shown how to use the service, for abuses would destroy it. "If this health service is rightly used and fostered it can become the envy of other countries, many of which incidentally, are carefully watching all the developments there."

Oestrogen therapy also lessened or eliminated the pain in the bones and produced general constitutional improvement. Albright concluded that bone formation is influenced by certain of the steroidal hormones. According to his hypothesis the steroidal hormones, promoting anabolism of protein, stimulate the osteoblasts, while the "sugar active" corticoids of the adrenal cortex, which inhibit protein anabolism, depress the activity of the osteoblasts. At the time of the menopause the laying down of organic matrix fails to keep pace with bone resorption and a reduction in bone substance results.

THE NUFFIELD FOUNDATION

THE Nuffield Foundation was brought into being for the purposes of promoting health, social well being, and the care and comfort of the aged poor. The trustees might thus have diffused the funds over a vast field of constructive endeavour. Instead, they wisely chose to concentrate them where the need was keenest, and the report for the first year¹—the first of the Foundation's second quinquennium—shows that this policy remains unchanged. In curative medicine, substantial grants have been promised for investigations of the modes of action and methods of synthesising 'Cortisone' and allied substances, and earlier projects in the fields of medicine (including social medicine), the natural sciences and the social sciences are promised further support. In its second five years the Foundation is concentrating particularly on fundamental research, notably in biology and sociology. In biology new grants have been made for studies of the factor determining the difference between cell types, of various types of learning system, of the control of regional determination in embryos and of the migration of cells in embryos and in adult life, of X ray analysis of crystals, and of tissue culture. In sociology grants are being made for investigations of the costs of founding and raising a family, of the patterns of family life, of the techniques of social surveys, and of the progress of 2000 Scottish 11 year olds, in the whole range of intelligence, who were first tested in 1947. By its fellowships and scholarships the Foundation has already done much to bring together teachers and others in the Commonwealth who might otherwise never have met, and it is now prepared to take a more direct hand in Commonwealth affairs by grants for research in overseas universities and similar institutions. (A Nuffield research professorship of mechanical engineering has already been endowed in New South Wales.) The Foundation now discharges its obligation to the aged through the National Corporation for the Care of Old People, but the report speaks pertinently of one aspect which is becoming more important.

"The increasing infirmity which often accompanies increasing age is a problem which every home for the able bodied—whether run by local authorities or by a voluntary society—has to face eventually, for, however spry the residents may be when admitted, some of them will decline into progressive ill health and will need much more physical help and more continuous care than a lightly staffed home can easily provide. At present it is nearly always impossible to gain admittance for a case of this kind into hospital. Indeed there is a real danger that in a few years from now many of the homes recently established may degenerate wholesale into medical slums, unless some simple and smooth transition can be effected to a stage half way between the two types of care provided respectively by the welfare and the health authorities."

Every project, says the report, is measured against its presumed, or even its speculative, contribution to the practical betterment of life. Perhaps the Foundation's most notable achievement has been to further rational humanitarianism.

HUMAN PERFORMANCE

Owing partly to war time research, we are fairly well placed to assess capacity for work and the causes of failing performance. During the late war Dr N H Mackworth conducted extensive studies of performance in a wide variety of tasks, and his findings, now published,¹ will be of interest far outside the confines of the psychological laboratory. Indeed he provides good evidence for the claim that "it has now become perfectly possible for experimental psychology to furnish assured and practical answers to questions concerning the limiting conditions under which even complex human operations can be maintained at a high level of accuracy with the minimum strain."

Dr Mackworth's studies, directed to the solution of problems arising in the extremely practical circumstances of armed conflict, owed much, as he points out, to the inventiveness and theoretical brilliance of K J W Craik whose influence on the present generation of experimental psychologists has been profound. The investigations fall into two main groups, concerned with (1) vigilance, and (2) the effects of environmental stress. In the work on vigilance the situations which, under Service conditions, had produced the problems were imitated closely in the laboratory. Two visual tasks were studied in connection with the difficulties found in 1943 in the routine use of radar, and auditory vigilance was studied in a third task simulating the operation of an 'Asdic' apparatus. In all three tasks significant deterioration, as measured by the number of signals missed was found during a two hour watch, beginning before the end of the first half hour. This deterioration was related to the difficulty of the task and the competence of the operator, for it did not take place when the initial level of missed signals was low. It could be prevented for the full two hour period by methods which kept alive the operator's interest—for instance, interruption of the task by the experimenter, or supplying knowledge of results—or by amphetamine sulphate in 10 mg dose. Dr Mackworth interprets these findings in terms of Pavlovian conditioning. The researches on environmental stress deal with the effects of harassing gas and of high atmospheric temperatures. Measurements were again made in several types of performance analogous to those required in the Services. An interesting finding was that deterioration in intensive forms of work was related logarithmically to increase of temperature. Physiological indices proved unreliable, except when the physiological state directly responsible for the deterioration could be identified.

The experiments are clearly described and should be readily capable of repetition and extension. The techniques are of a kind which ought to be of equal value in dealing with the problems of peace time.

THE first two years of the National Health Service were reviewed by Sir Andrew Davidson, chief medical officer of the Department of Health for Scotland, when he addressed the Society of Radiographers at a dinner in Edinburgh on June 23. A proper balance must, he said, be struck between the various elements of the service "more and more attention, for example, will need to be paid to those working in the homes of the people." Then, the quality of the service must be maintained at the highest standard, though "how this is to be done is difficult to see." A further requirement was to encourage research, both laboratory and sociological. Finally the public must be shown how to use the service, for abuses would destroy it. "If this health service is rightly used and fostered it can become the envy of other countries, many of which, incidentally are carefully watching all the developments there."

instinctive control of the body has not kept pace with man's needs and has ceased to be a proper guide. The time has come for reasoning man to employ his intellect in the care of his body. Bad use* controlled by instinct, shows its effects in all human ills. How then is the body to be put under the control of the conscious mind?

'The difficulty which has to be overcome is that 'sensory appreciation'† is defective. Misuse of the body is not realised. The wrong manner of use feels and seems to be right. To explain the way of misuse and to try to teach correct use *in action* fails, because as soon as man sets out to act he reverts to his instinctive way of action with its old misuse.

"The first step then (in re-education) is to stop the existing habitual reaction to an impulse. Attention must be concentrated on the manner in which the body is to work, and then the proper manner of working will be ensured and the act to be done may be allowed to come about.

"The relationship of the head to the neck and the neck to the back in activity, is held to be the chief factor in influencing the correct functioning of the body. Maintenance of the proper relationship at all times will ensure that all parts and organs of the body are working at their best. The mind is brought to bear on maintaining the proper relationship. That relationship, the 'primary control,' when maintained, will bring about the proper functioning of the rest of the body. By constant attention to the manner in which acts are performed, and especially constant attention to the head-neck-back relationship, the acquired manner of using the body will take the place of the wrong instinctive manner, and the body will function with the least effort and to the best advantage. And time by taking thought, man will convert a 'badly used himself' into a proper being."

TERMINOLOGY

Judge Clayden agreed that "in Alexander's book these ideas are tangled in a mass of words."

One of the chief difficulties in the whole action was to agree on a terminology which would ensure that the witnesses were talking about the same thing. Judge Clayden early established the terminology which he would employ.

"Mainly the evidence relates to the effect of good body mechanics on health and the prevention of disease, and to the possibility that alteration in posture or the 'better use' of Mr Alexander can improve body mechanics. When I use the term 'body mechanics' I shall use it as defined by Dr Goldthwait. 'The mechanics of the function of all the parts of the human body—bones, joints, muscles, viscera and nerves.' 'Posture,' I think, means the carriage of the limbs and body as a whole. Where in my view the question or the answer in evidence uses these words in some different sense, I shall mention. Mr Alexander and Dr Barlow shun the word posture to avoid confusion. I shall use for the technique of Mr Alexander the phrase 'Proper Use'."

Judge Clayden held that Mr Alexander's main principles were "that man's health is deteriorating that a main reason for this is the misuse of the body that the misuse of the body cannot be corrected (by ordinary methods) because of faulty sensory appreciation that 'proper use' can however be taught (by his method) that the maintenance of a proper head-neck relationship will to a large extent bring about 'proper use' that

* The term 'use' is employed by Alexander to denote the manner in which the parts of the body can be disposed in relationship to each other. The expression 'bad use' is employed by Alexander to denote patterns of movement which are instinctive, habitual, and thoughtless and which at the same time do not serve to promote optimum physiological functioning.

† Using this term, Alexander does not imply that sensation in the clinical sense (as determined for example by Head's tests of perception) is necessarily defective but that the perception of the body image in movement—the kinesthetic equivalent of movement—is often defective. Judge Clayden said later on this point. Sir Henry Dale and Professor Adrian speaking of the works of Sir Charles Sherrington agreed that there is a difficulty in forming a sensory appreciation of ordinary acts. In so far as faulty sensory appreciation is at the foundation of Mr Alexander's method it has not been shown that he is not right in alleging that it does exist and that its existence is a difficulty in the way of teaching another method of performing ordinary acts.

'proper use,' so taught, will improve health and prevent disease. Whether misuse of the body may be a cause of deterioration in health is so bound up with the question whether the Alexander technique can improve health and prevent disease that it has to be considered with those matters." These principles would, Judge Clayden suggested, have to be proved unsound if the defendants were to maintain their allegation that Mr Alexander's system "is quackery in the fields of physical education and medicine."

INFLUENCE OF BODY MECHANICS ON HEALTH

Considering in detail the evidence whether good body mechanics cannot improve health and prevent disease, and whether "proper use" (the Alexander technique) cannot bring about good body mechanics, Judge Clayden pointed out that "Prof Samson Wright is only prepared to concede that posture could have bad effects in cases of grave abnormality. Professor Adrian says that posture could obviously have bad effects, though he is not prepared to say what degree of abnormal posture would have those effects. He says that it is a commonly accepted view that good bodily functioning makes people less prone to disease. Sir Henry Dale says that 'such use of the body as a whole as keeps it in good health' may affect certain diseases.

"Dr Barlow in his evidence refers to various American authorities. Dr K G Hansson [1945], a doctor acknowledged by Dr Jokl to be an authority, reaches the following conclusion. 'The relation between health and body mechanics is soundly based on physical laws and on physiology. There is increasingly strong clinical evidence of posture and health being the cause and effect in many conditions.' The book *Essentials of Body Mechanics in Health and Disease*, of which the chief author is Dr Goldthwait, also an acknowledged expert, has passages which have been referred to in evidence on the effect of good body mechanics in health and in the prevention of disease. In the preface, pp v-vi, this is the view expressed: 'the proper training of the body for the greatest physical efficiency and the early recognition and treatment of faults which lead to disease are the chief business of the physician. In this prophylactic role of medicine, the development of good body mechanics plays an important part.' Dr Barlow also relies in support of his view upon *Principles and Practice of Physical Therapy*, edited by Professor Pemberton, and on the American Medical Association's *Handbook of Physical Therapy*, especially the passage at p 118, reading: 'Clinical evidence strongly suggests an intimate relationship between body mechanics and health.'

"These books by recognised authorities, or published with sanction of a recognised body, can only be used in support of the evidence of Dr Barlow. But the effect of all this evidence, and particularly the statement of Professor Adrian that it is a commonly accepted view that good bodily functioning makes people less prone to disease is that it certainly cannot be said that the defendants have proved that good body mechanics cannot lead to improvement in health and in a general sense to the prevention of disease."

THE HEAD-NECK RELATIONSHIP

The next stage in Judge Clayden's judgment dealt in detail with the relationship of the physiological researches of the late Professor Magnus to the Alexander method. This arose out of the following inaccurate statement by Jokl (1944):

'The cornerstone of Alexander's 'conscious control' theories is a discovery allegedly made by the late Professor Rudolph Magnus, who is said to have established the existence of 'the primary control of the individual.' This legendary 'primary control,' we are told, if properly brought

The picture of the work and cost of inpatient treatment as a whole given in table IV shows that there was little difference in the volume of the work undertaken in the two periods.

The analysis of ward costs shows that nearly 17.5% of the cost of medical beds and nearly 35.6% of the cost of surgical beds arises from the cost of the services given by the special departments, such as radiology, laboratories, physiotherapy and operating theatres.

TABLE V—ANALYSIS OF OUTPUT AND COST OF SPECIAL DEPARTMENTS

Unit		Oct 1, 1947 to July 4, 1948			July 5, 1948, to March 31, 1949		
		No. of units	Total cost	Unit cost	No. of units	Total cost	Unit cost
Biochemistry	Examination units	35,396	£ 2,891	s 11 d 8	48,998	£ 4,749	s 11 d 11
Pathological	Examination units	194,666	£ 18,081	s 11 d 11	206,481	£ 22,329	s 2 d 2
Operating theatres	Operating minutes	163,724	£ 19,744	s 2 d 5	196,255	£ 26,937	s 2 d 9
Physiotherapy	Treatments	42,163	£ 6,456	s 3 d 1	49,459	£ 6,867	s 2 d 9
X-ray	Examination units	193,842	£ 18,173	s 11 d 11	242,700	£ 21,005	s 1 d 9

Table V shows that the cost of each of these departments increased, but the increase is no doubt justified by the greater use made of them as shown by the higher output figures. The cost per unit of output has not risen unduly.

A distinct difference is evident between the comparatively small percentage increase in the unit cost of these treatment departments and the percentage increase in the weekly cost of inpatients. This difference is perhaps due partly to the ability of the departments to expand their work without having additional accommodation, whereas the output of the wards is closely limited by the number of beds.

Now that the United Oxford Hospitals is an administrative teaching group, it is possible to give details of the average costs per inpatient week of each of the constituent hospitals (table VI).

TABLE VI—SUMMARY OF WARD AND DEPARTMENTAL COST OF CONSTITUENT HOSPITALS FROM JULY 5, 1948, TO MARCH 31, 1949

	Cost per inpatient week	Number of beds	Average occupation
	£ s d		
Radcliffe Infirmary	15 12 6	505	454 90%
Churchill Hospital (an acute general hospital used as an integral part of the Radcliffe Infirmary but not for emergency work)	12 18 11	242	198 82%
Osler Pavillion (for tuberculous patients)	8 11 9	62	55 89%
Sunnyside Convalescent Home	6 12 9	36	28 75%
Cowley Road Hospital (for long stay cases)	6 18 7	250	237 95%
Slade Isolation Hospital	14 13 1	80	36 45%
Cold Arbour Hospital (for long stay tuberculous patients)	10 9 10	31	26 84%

The figures given in this article may not be typical for the country as a whole, but we hope they may serve as a guide to present hospital costs and as an indication that since the National Health Service started there has been no great increase in costs other than that occasioned by increases in salaries. They also show that for a hospital always working to capacity there can be little change in inpatient services, but that outpatient services have tended to increase, even in an already overcrowded department.

Points of View

THE ALEXANDER LIBEL ACTION

WILFRID BARLOW

M.A., B.M. Oxf.

LATE REGISTRAR, DEPARTMENT OF PHYSICAL MEDICINE,
MIDDLESEX HOSPITAL, LONDON

AN unsuccessful Supreme Court Appeal at the end of last year marked the close of a legal action which will be of interest, and possibly of importance, to those engaged in physical education and rehabilitation. The action touched on many procedures which are used in physical education and physical medicine, and expert opinions were given by eminent scientists, including Sir Henry Dale, O.M., F.R.S., Prof. L. D. Adrian, O.E.F.S. and Prof. Samson Wright. The publications put into court as evidence covered a large field of physiology and medicine.

The general background to the legal action has been well summarised by Mr. Norwood Cooker, K.C. (1949), but briefly the story is as follows. After some preliminary skirmishing, in and out of print, Dr. E. Jekel, the physical education officer of the South African government, published a strong attack in a government publication (1944) against a method of re-education evolved by an Australian, Mr. T. M. Alexander, about fifty years ago. The method has in recent years met with support in medical and educational circles. Dr. Jekel's article was put forward as a scientific analysis of Alexander's method, but no scientist would have said that it was written in a scientific manner. In the words of the Appeal Judges of the Supreme Court:

"It will be noticed that there is an appreciable quantum of malevolence in the article. It is not a dispassionate scientific analysis and consideration of the theories and claims in Alexander's books, but it directs ridicule and contempt not only at these theories and claims, but to some extent at the plaintiff in person."

The article was in fact couched in such terms that Alexander had little alternative but to request its withdrawal, and, when this was refused, to sue for defamation.

For many years I have studied the Alexander method, and I have written about it in the medical press (1945, 1946, 1947, 1948). For this reason I was asked to give evidence on its scientific soundness, and thus I attempted to do. It seemed to me that the good points of the method should as far as possible be defended, since these in my view far outweighed the weaknesses.

The case came up for trial in Johannesburg, before Mr. Justice Clayden, in 1948. In the previous year evidence had been taken on commission at South Africa House in London from a number of scientists in this country. The South African government attorney undertook the defence of the editors of the publication, and Mr. Oswald Pirow, K.C., was briefed as counsel for defence. Judgment was given for Alexander in the sum of £1000 with costs which ran into five figures, and this was confirmed in 1949 at the Supreme Court of Appeal, where it was found that the article was defamatory and not a fair representation of Alexander's theories.

In discussing the case, to avoid being controversial, I will quote from the actual judgment, which is a comprehensive document, summarising much of the 450,000 words given in evidence.

THE ALEXANDER METHOD

In his brief summary of the Alexander method Mr. Justice Clayden said:

"The underlying concept is that man in early time was a creature whose bodily functions were regulated by instinct, instinct properly adapted to his needs in the course of evolution. With the rapid advance of civilisation,

of Mr Alexander's technique in practice. In my findings on this part of the case I am not, I think, disregarding the very expert evidence which the defendants have led. The evidence could no doubt have discussed fully how far the Alexander technique, as applied in practice, could lead to good body mechanics. But through the misunderstanding of the technique expressed in the article, it has not on the whole been led in this regard.

"Dr Jokl, who gave evidence after the technique had been fully explained by the witnesses for the plaintiff, deals more directly with this matter. He denies that improvement in posture can bring about good body mechanics, but the grounds of the denial are, I consider, that improvement in posture brings about nothing, because it itself must be brought about by other factors, which are the factors responsible for improving the body mechanics.

"As against this evidence there is the evidence of Dr Barlow. In the field of medicine he does not pretend to speak with the authority of the English witnesses, or Dr Jokl. What he does maintain is that he, as a doctor, has studied the Alexander technique, and that he can therefore express with reason his views on the effects of it.

"It is here that the defendants find themselves in a difficulty. What has to be proved is that the technique cannot improve health and prevent the diseases which it claims to prevent. All of the witnesses for the defendants say that they cannot discover what Mr Alexander does to bring about 'proper use,' from his books: none of them has seen the technique in operation. The defendants have in my view to prove not only that the system as described is unsound but that as described and in operation it is unsound. They have to prove, on the issue which I am now considering, that persons who have undergone a course of instruction from Mr Alexander or his teachers, do not thereafter have improved body mechanics. Since none of the defendants' witnesses have seen such a person this is difficult. The evidence which is given as to the absence of effects of altered posture is not, I consider, evidence which can show this, because the posture which is spoken of is not 'proper use': it is not a position of advantage continuously maintained in movement. And the defendants do not offer proof that Mr Alexander's teaching does not in fact bring about improvement in body mechanics, whilst the plaintiff does offer such proof.

JUDGMENT ON THE SOUNDNESS OF THE METHOD

"In the absence of evidence showing on the balance of probability that 'proper use,' as taught, cannot improve body mechanics, and by reason of the evidence as to the effect of good body mechanics, the defendants have in my view failed to establish that the system is unsound. They have shown that Mr Alexander supports his technique by wrong physiological reasoning and by reference to work which almost certainly has nothing to do with it. But that in my view is not enough.

"In regard to the claims to prevent disease, the defendants in the article said that a claim was made to prevent practically every known disease. This was not, I think, claimed in the books. In regard to the diseases which he does claim to prevent, although I am far from saying that the evidence shows that claim to be sound, yet I consider that the defendants have not proved the negative: they had to prove they have not shown that what might lead to improved health might not prevent diseases for which the causes, or factors which build up resistance, are unknown. They have failed in my view to prove that the system cannot bring about the results which it does claim in the improvement of health and the prevention of disease, and again they have made matters worse by overstating the claims made for the system. The claim to improve health has not been shown to be baseless, even in the medical field."

DISCUSSION

I am not concerned here with the rest of the judgment, which covered a large field of legal matters. The important thing to decide is not whether Alexander may have given a misleading description of his work in the past but whether the actual method itself is going to repay further investigation in the future. The method rather than the man is what matters, and Alexander would be the first to agree with this.

Firstly, it is significant that the tremendous body of expert evidence which was brought by the defence, was unable to prove the method unsound. Rigorous statistical proof of the type demanded by the defendants for the method, is in fact available for extremely few medical procedures. And Professor Adrian pointed out that much of the customary handing out of bottles of medicine in general practice is scarcely scientific. If need not be stressed how great is the need now for a suitably controlled investigation of the method.

Secondly, it is necessary to consider seriously the novel suggestion that the head-neck relationship is of particular importance to the functioning of the whole organism. Although the *Zentralapparat* which Magnus described in *Körperstellung*, has been shown not to be of immediate relevance to Alexander's theories, nevertheless Magnus's Croonian and Cameronian lectures (1925, 1926) do draw attention to the importance of the head-neck relationship in man and work on the therapeutic implications of the tonic neck reflexes is being done on hemiplegics at the Bellevue Institute of Rehabilitation in New York (Corvath 1949). A recent report on this work states "The utilization of the tonic neck reflex in the rehabilitation of hemiplegic patients has, in our experience, had a marked effect on motivation. The reasons for its effectiveness are not obvious. We feel its implications rest, to a large extent, on a psychological basis."

Prof Raymond Dart, professor of anatomy in Johannesburg, and one of the most eminent anthropologists in the world, has recently given his backing to Alexander's views on the head-neck relationship (Dart 1946, 1947). I have discussed elsewhere in detail much of the other anatomical and physiological support (Barlow 1947, 1948). Recent work by two psychiatrists, Burrow (1949) and Reich (1949), confirms the importance of commencing re-education at the head end of the organism. And, perhaps most significant of all, there is the recent work of H. G. Wolff (1948). Writing on the head and neck muscles in anxiety he says:

"The patients in this group probably constituted the greatest number of any thus far considered. Records showed marked muscle contraction. The patient was unaware of any muscle contraction at the time. The symptoms are common signs of emotional tension and represent one of the major problems confronting the medical profession. The mechanism of the head symptoms was continuous muscle contraction. It may be added that even strong contraction of the muscles of the neck is often below the level of ordinary awareness. In some instances the contraction may be symbolic of withdrawing the head from a noxious agent or of stabilising the head on the shoulders for a charge against the threat. Experiments have demonstrated by electromyography that the sustained contraction of muscle is a source of pain and parasthesiae intense, dissatisfied, apprehensive, anxious people. Although presented as but one of the nine patient groups, it is numerically the largest."

Re-education by the Alexander method involves among other things teaching the patient to eliminate these neck tensions which are below the level of ordinary awareness and which distort the head-neck relationship. The association of emotion and muscle tension which is effected in the head-neck region may be one of the most important mechanisms by which emotion produces disease in many psychosomatic conditions.

into play, enables man to subject not only all his muscular actions but also the work of his internal organs to the supervision of his will."

Judge Clayden ruled quite definitely that Alexander made no claim to be able to teach people to control the working of their internal organs. He pointed out that the only claims to "control" which Alexander made, came in passages of which the following is an example.

For example, though it is not possible to control the viscera directly we can control directly the muscles of the abdominal wall which enclose the viscera." The manner in which Alexander links up "conscious control" with what he terms "the primary control," appears in the following passage from his writings

"Readers of my book, *The Use of the Self*, will remember that when I was experimenting with various ways of using myself in the attempt to improve the functioning of my vocal organs I discovered that a certain use of the head in relation to the neck, and of the neck in relation to the torso and the other parts of the organism, if consciously and continuously employed ensures, as was shown in my case, the establishment of a manner of use of the self as a whole which provides the best conditions for raising the standard of functioning of the various mechanisms, organs, and systems. I found that in practice this use of the parts, beginning with the use of the head in relation to the neck, constituted a primary control of the mechanisms as a whole, and that when I interfered with the employment of the primary control of my manner of use, this was always associated with a lowering of the standard of my general functioning. This brought me to realise that I had found a way by which we can judge whether the influence of our manner of use is affecting our general functioning adversely or otherwise, the criterion being whether or not this manner of use is interfering with the correct employment of the primary control. Thus 'primary control,' called by the late Professor Magnus the 'central control,' depends on a certain use of the head and neck in relation to the use of the rest of the body" (Alexander 1932)

Prof Samson Wright dealt carefully with this point and established that what Alexander was referring to as his "primary control" has nothing whatever to do with Magnus's concept of the *Zentralapparat* which refers to centres in the brain stem. Summing up on this point, the Appeal Judges said

"It requires an appreciable amount of anatomical and physiological knowledge to understand the experiments of Magnus and a considerable knowledge of technical terms to understand the published description of the experiments. The expert witnesses called for the defence say that Alexander's knowledge of these subjects is very limited and some of them suggest that he never read any description of Magnus's experiments but was given a second hand account of them which he did not understand. It is further more clear that before Magnus published the results of his experiments Alexander had already in his two earlier books attached great importance to the proper carriage of the head and neck. In the circumstances it is impossible to infer dishonesty rather than conceit and ignorance on the part of Alexander in relation to his claim to have anticipated Magnus in his discovery of a 'central control.' It seems to be not at all unlikely that he saw some resemblance between his theory about the head-neck relationship and Magnus's experiments, based upon some vague understanding of what he has been told about those experiments and came to the conclusion that what he had found out about the position of the head and neck was a discovery similar to the one made by Magnus.

Judge Clayden went on to point out that even if Alexander had misinterpreted Magnus in this one respect, this did not upset his own theory about the head-neck relationship. "Much of the evidence of the expert witnesses was given on the basis that Mr Alexander said that there was some centre in the body through which the mind could control the functions of the body. To show that Professor Magnus talked of nothing of the sort does not assist the defendants: such evidence proves only that what is not a basis of the Alexander

technique is not sound. When asked instead to accept that all that the 'primary control' meant was a relationship of the head to the neck, Sir Henry Dale, the intimate friend of Professor Magnus, says 'Magnus showed that the relation of the head to the neck had great reflex effects on all other parts of the body of the animal,' and agrees that Magnus put forward the phrase 'When the head moves, the body follows.' Professor Adrian says the same. He says that what Magnus showed in animals 'has not been shown in man,' and gives as a reason the fact that in four footed animals 'the head is in a different relation to the body than it is in man.' A passage from the book of Sir Charles Sherrington, *The Endeavour of Jean Fernel*, which reads 'To take a step is an affair not of this or that limb solely but of the total neuromuscular activity of the moment—not least of the hand and neck,' was a passage with which he agreed ‡

"Prof Samson Wright discussing the movement of the head in normal actions says 'That would have effects on certain muscles in other parts of the body,' and says it is 'extremely difficult to demonstrate any significant change in organs other than the muscles' by reason of the relation of the head to the neck. Dr Jöhl says that there might be a connection between what Professor Magnus showed in decerebrate animals and a changed posture in human beings by reason of a certain head-neck relationship, assuming that posture was changed, but he says he would require proof of that connection.

"In the world of science it is no doubt necessary for Mr Alexander to show that the maintenance of a certain head-neck relationship can in man improve the functioning of the body. In this case it is not necessary for him to do so. The defendants in their article have chosen to assert the contrary, and in this court have undertaken to prove that what they say is true. Challenges by witnesses to Mr Alexander to substantiate what he claims cannot prove the truth of what the defendants assert. Assuming that Mr Alexander can derive no support for his theory, that the maintenance of a certain head-neck relationship can have effects on the bodily functioning of man, from the works of Professor Magnus, because those works did not deal with man, still the defendants have to prove Mr Alexander wrong. It is a criterion then that he may wrongly claim support from those works but the proof that he is wrong has to be given otherwise.

DOES THE ALEXANDER METHOD IMPROVE BODY MECHANICS?

Judge Clayden continued "What has to be proved is that 'proper use' (the Alexander method) cannot bring about good body mechanics. Prof Samson Wright explains that a great many of the physiological reasons which Mr Alexander sets out in support of his technique are wrong. In his study of the technique which was only from the books, he has restricted himself entirely to Mr Alexander's physiology. Very little of the evidence relates to the possibility of Mr Alexander 'proper use' bringing about good body mechanics. When witnesses do speak of posture, or the head-neck relationship, they seem to be referring to some position which is adopted for a while for a particular purpose and not to the maintenance of a position of advantage to the body in all activity of the body. The emphasis which was placed by Dr Jöhl on the supposed 'primary conscious control,' and the alleged ability to control all organs, has I think caused the evidence to be mainly directed to showing how false such conceptions are. The evidence for the defendants is designed rather to support Dr Jöhl's article than to deal with the effect

‡ The sentence immediately preceding this in Sir Charles Sherrington's book reads 'Mr Alexander has done a service to the subject by insistently treating each act as involving the whole integrated individual—the whole psycho-physical man.'

money on housing. High costs were the worst feature of the problem, and anything that could be devised to reduce them would be welcomed. But in the meantime it was not in an apologetic frame of mind.

Vaccination of Hospital Staffs

In the House of Lords on June 22, Lord CLYDESMUIR drew attention to the danger of employing in or about fever hospitals people who had not been adequately protected against smallpox by vaccination. In the recent outbreak in Glasgow, of 18 confirmed cases, 3 had no vaccination scars. These patients all died, and they were the only patients who did die. Of the 12 who had vaccination scars 10 took a light form of smallpox. The remaining 2, who had a more severe attack but recovered, had been vaccinated eighteen and forty-three years respectively before they were attacked. In the outbreak in the West of Scotland mass vaccination would not have been necessary if it had been possible by administrative measures to check the disease more nearly to its source of outbreak. The disease was most usually found in an isolation hospital, and that should receive the first measure of protection. Vaccination was still compulsory in many circumstances, as for example when taking up an appointment abroad. Why should not the same care be extended to those exposed to risk in isolation hospitals, subject, of course, to conscientious objection?

Lord AMULREE quoted figures published by the old Metropolitan Asylums Board to show that in the twelve outbreaks of smallpox between 1892 and 1929, though there were 19,900 patients, there were only 15 cases of secondary infection among the people in charge of the patients. He thought that the reason for this comparative immunity was the board's insistence that their staffs should be successfully and regularly vaccinated. He would like to hear that administrative action was being taken to tighten things up so that no one should be employed in an infectious diseases hospital who had been not only vaccinated, but successfully vaccinated. Lord HADEN-GUEST agreed that the staffs of fever hospitals should be vaccinated, not only for their own protection but also because otherwise they might contract smallpox and give it to other people. He also agreed that vaccination should not be made compulsory for people who had conscientious objection. But it should be possible to see that people who did not submit to vaccination went neither to India as governors nor to infectious diseases hospitals, where they were likely to come into contact with smallpox.

Lord MORRISON, in the course of his reply, said the Government were fully alive to the need for adequate protective measures in hospitals against smallpox and other epidemic diseases. Special steps were being taken to bring the matter to the attention of hospital authorities in the National Health Service and to give them guidance on the measures to be taken. The problem of protection was not confined to fever hospitals, any rules for protection should also be applied to general hospitals, and indeed to workers in other branches of the health service as well. The National Health Service Act provided for the repeal of compulsory vaccination, and the Government did not think it right to impose compulsion on nurses when it did not apply to the rest of the community. This might well adversely affect recruitment to the nursing profession, and the difficulty might be even greater with domestic staff who tended to move freely from hospital to other work. Nevertheless, the Government were in full sympathy with the end which Lord Clydesmur had in view, and after consultation with local authorities, medical officers of health, and others concerned instructions were being issued to the hospitals in England and Wales and Scotland laying down that where staff was likely to be subject to special risk, both in general hospitals, children's hospitals, and infectious diseases hospitals, all recruits to the staff would be offered vaccination unless they could present clear evidence of having been recently vaccinated. Staffs already in posts would be offered re-vaccination from time to time, at least once in every three years. There might have to be some modification of these arrangements for transient employees whose hospital service was short and who were not brought into contact with

patients. This, however, would be the only exception. Experience suggested that staff whose duties brought them into contact with patients were unlikely to refuse vaccination, especially when care was taken—as it would be—to present the offer suitably and make arrangements for carrying out the vaccination without delay. If a nurse did decline to be vaccinated, the hospital authorities would arrange for her to be employed on duties where the risk of contact was reduced to a minimum.

All hospitals would be required to maintain accurate and up to date records showing the vaccination position of each member of the staff. This would ensure that prompt and effective action could be taken as soon as a case of, or a contact with, smallpox arrived in hospital. When that happened vaccination or re-vaccination would be offered immediately to all members of the staff and at the same time, their vaccination position would be checked so as to remove from any risk of contact anyone who was not protected. This would apply not only to nurses but to domestics, ambulance attendants, and anyone else at the hospital who was exposed to the risk of contact.

Hospitals which were actually designated for the admission of smallpox patients should an outbreak occur, were in a special category. As an invariable rule their staffs must be adequately protected by periodic vaccination and also by re-vaccination when, or if possible before, the first case was admitted. The staff of these smallpox units were normally volunteers who had offered their services on the clear understanding that their vaccinal state would be maintained at a high level by re-vaccination and the question of compulsion did not, therefore, really arise. What had been said applied primarily to smallpox, but it was now the normal practice for hospital nurses to be immunised against diphtheria, and typhoid and paratyphoid fevers. In addition, to help to protect nurses against tuberculosis, they were now being offered inoculation with BCG vaccine in appropriate cases.

Hospital authorities had also been reminded of the necessity for working closely in all matters regarding the control of epidemic diseases with the medical officers of health. It was essential that such officers should be warned at once when there was any suspicion of a case of smallpox in a hospital, or of any other similar disease which might be the forerunner of an epidemic.

The Government believed that most of the measures outlined fell within what was already recognised to be good hospital practice, and that they were taken as a matter of routine by most hospital authorities. The new instructions would ensure that the measures were taken by all hospitals and this would reduce the risk to hospital staffs to the minimum. It was important, however, that this problem should be seen in its true perspective. While the Government were instructing hospital authorities to take every necessary precaution, the actual risk of hospital staffs being exposed to smallpox had proved in practice to be slight. There were peculiar circumstances about the recent unfortunate outbreak in Glasgow, and while this was not a matter for prediction, there was no reason to fear repetition. The Government did not feel that they would be justified, as a result of this one case, in taking the extreme step of enforcing compulsory vaccination on one class of the community—nurses and other members of the hospital staff—who, perhaps more than any other, were fully conscious of the value of protective measures and could be trusted to take a responsible view of their duty to themselves and to the rest of the community.

Future of Kingston Victoria Hospital

In the House of Commons on June 21, Mr J. A. BOYD-CARPENTER asked whether the Kingston Victoria Hospital was to continue as a separate entity, or be merged as the maternity wing of a larger county hospital. He appreciated that there were complaints for which specialist treatment in a larger hospital was necessary, but there were also cases where the patient was right in desiring treatment in a smaller hospital in which it was possible for the general practitioner, who had had general care of the case for years, could continue the treatment.

Thirdly, it appears that if Alexander's observations on "defective kinaesthesia" are correct, much of the work at present being done in the field of rehabilitation and remedial exercises is misapplied, since the problem is not one of physical education but of *psycho* physical education. The state of present re-educational methods has been shown to be unsatisfactory by Laplace and Nicholson (1936) in one of the best studies available. They found that out of 50 patients only 23 showed any improvement after posture training, and, of these, only 8 retained any improvement after twelve months. This result is to be expected when the problem is seen as one of physical education. Faulty habits of "use" cannot be altered in any lasting manner until there has been 'kinaesthetic re-education'—a reeducation of the patient's conception of what constitutes the right amount of tension to use in his daily activities. In many spheres of life, the complete interrelationship of mind and body is now accepted: there appears to be no reason why mind-body dichotomy should be expected to work

successfully in the spheres of physical medicine and physical education if it has been discarded as inadequate in other spheres.

Parliament

The Housing Situation

THE only person in the country who was satisfied with the housing situation, Lord LLEWELLYN suggested in opening this debate in the House of Lords on June 21, was the Minister of Health. But this ministerial complacency was not shared up and down the country. In his budget speech Sir Stafford Cripps had said that the Government had decided that the housing programme would run at 200,000 houses for the next three years, and after the indecision shown since the devaluation crisis Lord Llewellyn welcomed a firm target though he regretted it was not higher. Apart from a possible increase of imported raw materials, he himself could not see why we had to alter our housing programme because of the devaluation crisis. In the face of the crying need for more houses it was surely one of the last things upon which expenditure should be cut.

The ARCHBISHOP OF YORK deplored that the present policy of the Government was not reducing the population in the slums. Year by year the slums were increasing in number and in horror. He was not a critic of the Government's main housing policy. He agreed that it was a remarkable achievement to have built or made habitable over a million houses. He was sure the Minister of Health was right in first building houses to let rather than to sell. But the time had come, he affirmed, when we needed some new departure which would bring influence to bear directly upon the slums. The war, he continued, had interrupted the campaign against the slums. True, its first effect had been to destroy some of the worst slums through the bombardment from the air. But almost immediately new slums came into existence, for the people driven from their houses had to find refuge in houses which were already overcrowded. He doubted whether at any time in the last hundred years overcrowding had been so grave and the slums so disastrous as at present. For the housing problem, he pointed out, affected almost every kind of social problem. It affected the health of the people, the greatest increase in tuberculosis had taken place in these congested areas. We were trying to improve the education of the country, the children from overcrowded districts were backward, for they had no opportunities for doing their homework, and at night they were often disturbed. Juvenile delinquency was also closely linked with housing, children from overcrowded homes spent their evenings in the street where they easily dropped into gangs out of sheer restlessness. Unhappy marriages were often due to the long wait for a house or to sharing a home with in-laws. If there was another evacuation from the slums tomorrow there would once more be an outcry at the children who were unsatisfactory in their cleanliness and their habits. We should not blame the parents but the conditions under which these children were forced to live. It was all the more deplorable that many wage-earners with large families could not afford

what new houses there were. He recognised that it would be useless to ask the Government to increase their subsidies, but he did suggest that some people living in these subsidised houses could afford to pay higher rent. Could the subsidy not be gradually shifted over to help those unable to pay the present rents? He feared that sometimes almost out of despair we were apt to acquiesce in the existence of slums. He knew the Minister of Health as a man of dynamic energy, and he appealed to him to divert that energy to dealing with the problem of the slums.

VISCOUNT SAMUEL, who spoke for the Liberal peers in the absence of Lord Amulree, urged his listeners not to allow themselves to be fogged by a cloud of statistics. They must judge by results. The people were not sufficiently housed and they could not get away from that. The Government had rendered many services to the nation in improving social conditions, but in housing they must bear the blame for a failure which was evident and which inflicted the greatest injury upon the people.

The EARL OF SELKIRK believed that future historians would look with dismay on a generation who were competent aviators, who were moving from radio to television, who were on the verge of the atomic age, but who could not provide themselves with reasonable houses. Glasgow for instance had a waiting list of 100,000. The rate of building was about 4000 a year. Thus anyone who married in Glasgow tomorrow could expect a house in time for their silver wedding. The cost of the 200,000 houses which it was planned to build was about half of what was spent in this country on gambling and probably a sixth of what was spent on tobacco and alcohol.

LORD MONTAGU OF BEAULIEU gave a constructive turn to the debate by describing the houses now being built at Orpington, Kent, by the L.C.C. The builder had contracted to build 100 of these houses in 100 days with only 45 workpeople. They were constructed of cement blocks made of a mixture of shingle, sand, and cement. The blocks were made in moulds of any size needed to build a house, and one man could in one day make the equivalent of 2000 bricks. Furthermore these houses needed no timber and were cheaper to build than pre-fabs, costing about £1200-£1300.

In his reply Lord ADDISON said he would blame no government for not solving the housing problem in a year or two. If we continued to build 200,000 houses a year for the next generation then we should have begun to make a considerable impression on the problem. That was the kind of problem it was. We had 253,000 workpeople employed on building houses. A further 250,000 were repairing houses. We were also building new factories, new power stations, schools, and hospitals. Which of these, he asked, were the noble Lords going to chop off? Since the war over a million new homes had been provided, including 612,659 new houses in England and Wales and 73,160 in Scotland. New standards of living had rightly altered the character of the demand, and we were spending an unprecedented amount of

onev on housing High costs were the worst feature the problem, and anything that could be devised to duce them would be welcomed But in the meantime e was not in an apologetic frame of mind

Vaccination of Hospital Staffs

In the House of Lords on June 22, Lord CLYDESMUR drew attention to the danger of employing in or about ever hospitals people who had not been adequately protected against smallpox by vaccination In the recent outbreak in Glasgow, of 18 confirmed cases, had no vaccination scars These patients all died, and they were the only patients who did die Of the 2 who had vaccination scars 10 took a light form of mallpox The remaining 2, who had a more severe attack but recovered, had been vaccinated eighteen and forty-three years respectively before they were attacked In the outbreak in the West of Scotland mass vaccination would not have been necessary if it had been possible by administrative measures to check the disease more nearly to its source of outbreak The disease was most usually found in an isolation hospital, and that should receive the first measure of protection Vaccination was still compulsory in many circumstances as for example when taking up an appointment abroad Why should not the same care be extended to those exposed to risk in isolation hospitals, subject, of course, to conscientious objection?

Lord AMULREE quoted figures published by the old Metropolitan Asylums Board to show that in the twelve outbreaks of smallpox between 1892 and 1929, though there were 19,000 patients, there were only 15 cases of secondary infection among the people in charge of the patients He thought that the reason for this comparative immunity was the board's insistence that their staffs should be successfully and regularly vaccinated He would like to hear that administrative action was being taken to tighten things up so that no-one should be employed in an infectious diseases hospital who had been not only vaccinated, but successfully vaccinated Lord HADEN-GUEST agreed that the staffs of fever hospitals should be vaccinated, not only for their own protection but also because otherwise they might contract smallpox and give it to other people He also agreed that vaccination should not be made compulsory for people who had conscientious objection But it should be possible to see that people who did not submit to vaccination went neither to India as governors nor to infectious diseases hospitals, where they were likely to come into contact with smallpox

Lord MORRISON, in the course of his reply, said the Government were fully alive to the need for adequate protective measures in hospitals against smallpox and other epidemic diseases Special steps were being taken to bring the matter to the attention of hospital authorities in the National Health Service and to give them guidance on the measures to be taken The problem of protection was not confined to fever hospitals, and rules for protection should also be applied to general hospitals, and indeed to workers in other branches of the health service as well The National Health Service Act provided for the repeal of compulsory vaccination, and the Government did not think it right to impose compulsion on nurses when it did not apply to the rest of the community This might well adversely affect recruitment to the nursing profession, and the difficulty might be even greater with domestic staff, who tended to move freely from hospital to other work Nevertheless, the Government were in full sympathy with the end which Lord Clydesmur had in view, and after consultation with local authorities, medical officers of health, and others concerned instructions were being issued to the hospitals in England and Wales and Scotland laying down that where staff was likely to be subject to special risk, both in general hospitals, children's hospitals, and infectious diseases hospitals, all recruits to the staff would be offered vaccination unless they could present clear evidence of having been recently vaccinated Staffs already in posts would be offered re-vaccination from time to time, at least once in every three years There might have to be some modification of these arrangements for transient employees whose hospital service was short and who were not brought into contact with

patients This, however, would be the only exception Experience suggested that staff whose duties brought them into contact with patients were unlikely to refuse vaccination, especially when care was taken—as it would be—to present the offer suitably and make arrangements for carrying out the vaccination without delay If a nurse did decline to be vaccinated, the hospital authorities would arrange for her to be employed on duties where the risk of contact was reduced to a minimum

All hospitals would be required to maintain accurate and up-to-date records showing the vaccination position of each member of the staff This would ensure that prompt and effective action could be taken as soon as a case of, or a contact with, smallpox arrived in hospital When that happened vaccination or re-vaccination would be offered immediately to all members of the staff and at the same time, their vaccination position would be checked so as to remove from any risk of contact anyone who was not protected This would apply not only to nurses but to domestics, ambulance attendants, and anyone else at the hospital who was exposed to the risk of contact.

Hospitals which were actually designated for the admission of smallpox patients should an outbreak occur, were in a special category As an invariable rule their staffs must be adequately protected by periodic vaccination and also by re-vaccination when, or if possible before, the first case was admitted The staff of these smallpox units were normally volunteers who had offered their services on the clear understanding that their vaccinal state would be maintained at a high level by re-vaccination and the question of compulsion did not, therefore, really arise What had been said applied primarily to smallpox, but it was now the normal practice for hospital nurses to be immunised against diphtheria, and typhoid and paratyphoid fevers In addition, to help to protect nurses against tuberculosis, they were now being offered inoculation with BCG vaccine in appropriate cases

Hospital authorities had also been reminded of the necessity for working closely in all matters regarding the control of epidemic diseases with the medical officers of health It was essential that such officers should be warned at once when there was any suspicion of a case of smallpox in a hospital, or of any other similar disease which might be the forerunner of an epidemic

The Government believed that most of the measures outlined fell within what was already recognised to be good hospital practice, and that they were taken as a matter of routine by most hospital authorities The new instructions would ensure that the measures were taken by all hospitals and thus would reduce the risk to hospital staffs to the minimum It was important, however, that this problem should be seen in its true perspective While the Government were instructing hospital authorities to take every necessary precaution, the actual risk of hospital staffs being exposed to smallpox had proved in practice to be slight There were peculiar circumstances about the recent unfortunate outbreak in Glasgow, and while this was not a matter for prediction, there was no reason to fear repetition The Government did not feel that they would be justified, as a result of this one case, in taking the extreme step of enforcing compulsory vaccination on one class of the community—nurses and other members of the hospital staff—who, perhaps more than any other, were fully conscious of the value of protective measures and could be trusted to take a responsible view of their duty to themselves and to the rest of the community

Future of Kingston Victoria Hospital

In the House of Commons on June 21, Mr J. A. BOYD-CARPENTER asked whether the Kingston Victoria Hospital was to continue as a separate entity, or be merged as the maternity wing of a larger county hospital He appreciated that there were complaints for which specialist treatment in a larger hospital was necessary, but there were also cases where the patient was right in desiring treatment in a smaller hospital in which it was possible for the general practitioner, who had had general care of the case for years, could continue the treatment.

Thirdly, it appears that if Alexander's observations on "defective kinaesthesia" are correct, much of the work at present being done in the field of rehabilitation and remedial exercises is misapplied, since the problem is not one of physical education but of *psycho* physical education. The state of present re-educational methods has been shown to be unsatisfactory by Laplace and Nicholson (1936) in one of the best studies available. They found that out of 50 patients only 23 showed any improvement after posture training, and, of these, only 8 retained any improvement after twelve months. This result is to be expected when the problem is seen as one of physical education. Faulty habits of "use" cannot be altered in any lasting manner until there has been "kinaesthetic re-education"—a re-education of the patient's conception of what constitutes the right amount of tension to use in his daily activities. In many spheres of life, the complete interrelationship of mind and body is now accepted: there appears to be no reason why mind-body dichotomy should be expected to work

successfully in the spheres of physical medicine and physical education if it has been discarded as inadequate in other spheres.

Parliament

The Housing Situation

THE only person in the country who was satisfied with the housing situation, Lord LLEWELIN suggested in opening this debate in the House of Lords on June 21, was the Minister of Health. But this ministerial complacency was not shared up and down the country. In his budget speech Sir Stafford Cripps had said that the Government had decided that the housing programme would run at 200,000 houses for the next three years, and after the indecision shown since the devaluation crisis Lord Llewellyn welcomed a firm target though he regretted it was not higher. Apart from a possible increase of imported raw materials, he himself could not see why we had to alter our housing programme because of the devaluation crisis. In the face of the crying need for more houses it was surely one of the last things upon which expenditure should be cut.

The ARCHBISHOP OF YORK deplored that the present policy of the Government was not reducing the population in the slums. Year by year the slums were increasing in number and in horror. He was not a critic of the Government's main housing policy. He agreed that it was a remarkable achievement to have built or made habitable over a million houses. He was sure the Minister of Health was right in first building houses to let rather than to sell. But the time had come, he affirmed, when we needed some new departure which would bring influence to bear directly upon the slums. The war, he continued, had interrupted the campaign against the slums. True, its first effect had been to destroy some of the worst slums through the bombardment from the air. But almost immediately new slums came into existence, for the people driven from their houses had to find refuge in houses which were already overcrowded. He doubted whether at any time in the last hundred years overcrowding had been so grave and the slums so disastrous as at present. For the housing problem, he pointed out, affected almost every kind of social problem. It affected the health of the people, the greatest increase in tuberculosis had taken place in these congested areas. We were trying to improve the education of the country, the children from overcrowded districts were backward, for they had no opportunities for doing their homework and at night they were often disturbed. Juvenile delinquency was also closely linked with housing, children from overcrowded homes spent their evenings in the street where they easily dropped into gangs out of sheer restlessness. Unhappy marriages were often due to the long wait for a house or to sharing a home with in-laws. If there was another evacuation from the slums tomorrow there would once more be an outcry at the children who were unsatisfactory in their cleanliness and their habits. We should not blame the parents but the conditions under which these children were forced to live. It was all the more deplorable that many wage-earners with large families could not afford

what new houses there were. He recognised that it would be useless to ask the Government to increase their subsidies, but he did suggest that some people living in these subsidised houses could afford to pay higher rent. Could the subsidy not be gradually shifted over to help those unable to pay the present rents? He feared that sometimes almost out of despair we were apt to acquiesce in the existence of slums. He knew the Minister of Health as a man of dynamic energy, and he appealed to him to divert that energy to dealing with the problem of the slums.

VISCOUNT SAMUEL, who spoke for the Liberal peers in the absence of Lord Amulree, urged his listeners not to allow themselves to be fogged by a cloud of statistics. They must judge by results. The people were not sufficiently housed and they could not get away from that. The Government had rendered many services to the nation in improving social conditions, but in housing they must bear the blame for a failure which was evident and which inflicted the greatest injury upon the people.

The EARL OF SELKIRK believed that future historians would look with dismay on a generation who were competent aviators, who were moving from radio to television, who were on the verge of the atomic age, but who could not provide themselves with reasonable houses. Glasgow, for instance, had a waiting list of 100,000. The rate of building was about 4000 a year. Thus anyone who married in Glasgow tomorrow could expect a house in time for their silver wedding. The cost of the 200,000 houses which it was planned to build was about half of what was spent in this country on gambling and probably a sixth of what was spent on tobacco and alcohol.

LORD MONTAGU OF BEAULIEU gave a constructive turn to the debate by describing the houses now being built at Orpington, Kent, by the L.C.C. The builders had contracted to build 100 of these houses in 100 days with only 45 workpeople. They were constructed of cement blocks made of a mixture of shingle, sand, and cement. The blocks were made in moulds of any size needed to build a house, and one man could in one day make the equivalent of 2000 bricks. Furthermore these houses needed no timber and were cheaper to build than prefabs, costing about £1200-£1300.

In his reply Lord ADDISON said he would blame no government for not solving the housing problem in a year or two. If we continued to build 200,000 houses a year for the next generation then we should have begun to make a considerable impression on the problem. That was the kind of problem it was. We had 253,000 workpeople employed on building houses. A further 250,000 were repairing houses. We were also building new factories, new power stations, schools, and hospitals. Which of these, he asked, were the noble Lords going to chop off? Since the war over a million new homes had been provided, including 612,559 new houses in England and Wales and 73,100 in Scotland. New standards of living had rightly altered the character of the demand, and we were spending an unprecedented amount of

on housing. High costs were the worst feature of the problem, and anything that could be devised to meet them would be welcomed. But in the meantime it was not in an apologetic frame of mind.

Vaccination of Hospital Staffs

In the House of Lords on June 22, Lord CLYDESMUIR drew attention to the danger of employing in or about hospitals people who had not been adequately protected against smallpox by vaccination. In the recent outbreak in Glasgow, of 18 confirmed cases, 14 had no vaccination scars. These patients all died, and they were the only patients who did die. Of the 4 who had vaccination scars 10 took a light form of smallpox. The remaining 2, who had a more severe attack but recovered, had been vaccinated eighteen and forty-three years respectively before they were vaccinated. In the outbreak in the West of Scotland vaccination would not have been necessary if it had been possible by administrative measures to check the disease more nearly to its source of outbreak. The disease was most usually found in an isolation hospital, and that should receive the first measure of protection. Vaccination was still compulsory in many circumstances, for example when taking up an appointment abroad, but should not the same care be extended to those exposed to risk in isolation hospitals, subject, of course, to conscientious objection?

Lord AMULREE quoted figures published by the old Metropolitan Asylums Board to show that in the twelve outbreaks of smallpox between 1892 and 1920, though there were 19,900 patients, there were only 15 cases of secondary infection among the people in charge of the patients. He thought that the reason for this comparative immunity was the board's insistence that their staffs should be successfully and regularly vaccinated. He would like to hear that administrative action was being taken to tighten things up so that no one should be employed in an infectious diseases hospital who had been not only vaccinated, but successfully vaccinated. Lord RADEN-GUEST agreed that the staffs of fever hospitals should be vaccinated, not only for their own protection but also because otherwise they might contract smallpox and give it to other people. He also agreed that vaccination should not be made compulsory for people who had conscientious objection. But it should be possible to see that people who did not submit to vaccination went neither to India as governors nor to infectious diseases hospitals, where they were likely to come into contact with smallpox.

Lord MORRISON, in the course of his reply, said the Government were fully alive to the need for adequate protective measures in hospitals against smallpox and other epidemic diseases. Special steps were being taken to bring the matter to the attention of hospital authorities in the National Health Service and to give them guidance on the measures to be taken. The problem of protection was not confined to fever hospitals, any rules for protection should also be applied to general hospitals, and indeed to workers in other branches of the health service as well. The National Health Service Act provided for the repeal of compulsory vaccination and the Government did not think it right to impose compulsion on nurses when it did not apply to the rest of the community. This might well adversely affect recruitment to the nursing profession, and the difficulty might be even greater with domestic staff, who tended to move freely from hospital to other work. Nevertheless, the Government were in full sympathy with the end which Lord Clydesmuir had in view, and after consultation with local authorities, medical officers of health, and others concerned instructions were being issued to the hospitals in England and Wales and Scotland laying down that where staff was likely to be subject to special risk, both in general hospitals, children's hospitals, and infectious diseases hospitals, all recruits to the staff would be offered vaccination unless they could present clear evidence of having been recently vaccinated. Staffs already in posts would be offered re-vaccination from time to time, at least once in every three years. There might have to be some modification of these arrangements for transient employees whose hospital service was short and who were not brought into contact with

patients. This, however, would be the only exception. Experience suggested that staff whose duties brought them into contact with patients were unlikely to refuse vaccination, especially when care was taken—as it would be—to present the offer suitably and make arrangements for carrying out the vaccination without delay. If a nurse did decline to be vaccinated, the hospital authorities would arrange for her to be employed on duties where the risk of contact was reduced to a minimum.

All hospitals would be required to maintain accurate and up to date records showing the vaccination position of each member of the staff. This would ensure that prompt and effective action could be taken as soon as a case of, or a contact with, smallpox arrived in hospital. When that happened vaccination or re-vaccination would be offered immediately to all members of the staff and at the same time their vaccination position would be checked so as to remove from any risk of contact anyone who was not protected. This would apply not only to nurses but to domestics, ambulance attendants and anyone else at the hospital who was exposed to the risk of contact.

Hospitals which were actually designated for the admission of smallpox patients should an outbreak occur, were in a special category. As an invariable rule their staffs must be adequately protected by periodic vaccination and also by re-vaccination when, or if possible before, the first case was admitted. The staff of these smallpox units were normally volunteers who had offered their services on the clear understanding that their vaccinal state would be maintained at a high level by re-vaccination and the question of compulsion did not, therefore, really arise. What had been said applied primarily to smallpox, but it was now the normal practice for hospital nurses to be immunised against diphtheria, and typhoid and paratyphoid fevers. In addition, to help to protect nurses against tuberculosis, they were now being offered inoculation with BCG vaccine in appropriate cases.

Hospital authorities had also been reminded of the necessity for working closely in all matters regarding the control of epidemic diseases with the medical officers of health. It was essential that such officers should be warned at once when there was any suspicion of a case of smallpox in a hospital, or of any other similar disease which might be the forerunner of an epidemic.

The Government believed that most of the measures outlined fell within what was already recognised to be good hospital practice, and that they were taken as a matter of routine by most hospital authorities. The new instructions would ensure that the measures were taken by all hospitals and this would reduce the risk to hospital staffs to the minimum. It was important, however, that this problem should be seen in its true perspective. While the Government were instructing hospital authorities to take every necessary precaution, the actual risk of hospital staffs being exposed to smallpox had proved in practice to be slight. There were peculiar circumstances about the recent unfortunate outbreak in Glasgow, and while this was not a matter for prediction, there was no reason to fear repetition. The Government did not feel that they would be justified, as a result of this one case, in taking the extreme step of enforcing compulsory vaccination on one class of the community—nurses and other members of the hospital staff—who, perhaps more than any other, were fully conscious of the value of protective measures and could be trusted to take a responsible view of their duty to themselves and to the rest of the community.

Future of Kingston Victoria Hospital

In the House of Commons on June 21, Mr J. A. BOYD CARPENTER asked whether the Kingston Victoria Hospital was to continue as a separate entity, or be merged as the maternity wing of a larger county hospital. He appreciated that there were complaints for which specialist treatment in a larger hospital was necessary, but there were also cases where the patient was right in desiring treatment in a smaller hospital in which it was possible for the general practitioner, who had had general care of the case for years, could continue the treatment.

Kingston Victoria Hospital was a hospital of that kind. Public opinion in the district was all but unanimous, and medical opinion entirely unanimous, that this hospital should continue as a small general practitioner unit, but the Minister of Health had refused to take steps to save the hospital. Those who opposed the extinction of the hospital had sought to meet the legitimate concern of the regional hospital board by putting forward a compromise proposal under which the annexe of the Victoria Hospital would be used as the maternity wing. That had been inspected by all the competent people, and he was told that a distinguished gynaecologist, who would be in charge of the maternity unit, had indicated that in his view these premises would be satisfactory.

Dr CHARLES HILL said that everyone realised the responsibility of the Minister of Health for specialist services but it was in the public interest that there should be an ample provision of general-practitioner beds where general practitioners could, in the interests of those patients whose domestic and housing conditions made it necessary, treat their own patients in hospital surroundings.

Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, said the Minister had expressed quite clearly in circulars to the regional hospital boards his desire that general practitioners should not be excluded from small hospitals. He was glad that the amended proposals had been put forward by the regional hospital board taking that point into account. There were bound to arise differences of opinion in a particular area when the hospital board was attempting to secure the best possible use of the accommodation available, but the boards did attempt to reach reasonable conclusions. It was proposed to use the Kingston Victoria Hospital for a most vital purpose. In this area there was an urgent need for more maternity accommodation, and this proposal would affect quite a number of hospitals within the group. It meant for the group as a whole an increase from 81 to 96 maternity beds and from 37 to 40 gynaecological beds. The board in their revised proposals suggested the Surbiton annexe should be used for general medical cases—this would be open to general practitioners—and also that, as far as practicable, there should be posts offered for clinical assistants. But Mr Blenkinsop could not give a guarantee that every practitioner who at present had access to the Kingston Victoria Hospital would automatically secure a clinical assistantship. The desire was that within what was regarded as the proper clinical needs of the area the general practitioner should not be cut off from hospital work. It seemed to the Minister that these modified proposals adequately covered that point.

QUESTION TIME

Medical Services in Malaya

Colonel M STODDART SCOTT asked the Secretary of State for War if additional medical personnel had arrived in Malaya and whether he was satisfied that an adequate service was being provided.—Mr JOHN STRACHEY replied. During my recent visit I naturally looked into this matter very carefully. I think that the supply of specialists in Malaya is completely satisfactory. I found no hospital or unit which felt they were short of specialists, although it is true to say that in some cases they are short of general practitioner establishment. For example, the base hospital at Singapore is short of general practitioners in the sense that they are below establishment. There are quite enough practitioners to cope with the work in hand now, and no man is suffering for lack of general practitioner attention. However, I should like to get the number up a bit towards establishment in case the present wonderful health record of the troops does not continue quite as well. That we are attempting to do. The hon. and gallant gentleman will appreciate the difficulty of getting general practitioners at the moment, but we are sending more out.

Mr STRACHEY added that the health of the troops in the Far Eastern Command was excellent. The medical authorities had assured him that, taking one thing with another, the sickness rate was below, rather than above, that of the troops in the United Kingdom.

Advertising of Hospital Staff Vacancies

Sir HUGH LUCAS TOOTH asked the Minister of Health what was the cost, for any convenient area, of advertising in the press for vacancies on hospital staffs.—Mr A. BEVAN replied. The total cost during 1949-50 for all non-teaching hospitals in England and Wales was approximately £500,000.

Sir HUGH LUCAS TOOTH. Does not the Minister think it is a very large sum to pay to newspaper proprietors? Is he aware that in many cases these advertisements are almost duplications of one another with perhaps one word changed?—Mr BEVAN. I have already called the attention of regional hospital boards to my view that this is an excessive sum but it must be remembered that when the service was built up very large numbers of additional domestic staff were being recruited for the hospitals and that advertisement was necessary for that purpose. For two or three years I was pressed to increase the employment of domestic staff in hospitals and we succeeded in doing this. This was one of the ways of doing it.

Grading of Hospital Medical Officers

Mr G. H. OLIVER asked the Minister whether he was aware that doctors who were refused consultant status and graded as senior medical officers under the National Health Act had been compelled, in order to obtain posts carrying consultant status, to leave their hospitals and go to others and that the vacancies thus created had been advertised and filled not by doctors graded as senior medical officers but by consultants, and whether this practice had his approval.—Mr BEVAN replied. During this transitional period some posts graded for consultants are inevitably held by individuals who have been graded only as senior hospital medical officers. It must, of course, always be open to these officers to seek advertised consultant appointments at their own or other hospitals, if they think they are likely to qualify for them. Mr OLIVER. Does not the Minister appreciate that it causes a great deal of unnecessary hardship if doctors must move to obtain a status to which they ought to have been graded in the first place?—Mr BEVAN. On the contrary, it would cause very considerable hardship if a doctor who had already been graded as a senior medical officer could never have a chance of being regarded as a consultant.

Queen Victoria Hospital, Morecambe

Sir IAN FRASER asked the Minister why this hospital had been converted from a general practitioner hospital to a surgical hospital.—Mr BEVAN replied. I am informed that this was a hospital where specialist work was done by general practitioners supported by visiting specialists. The change made by the regional board has been to give specialists charge of this work.

Dental Students

In answer to a question Mr BEVAN stated that the annual pre-war intake of students in dental schools in the United Kingdom was about 400. The corresponding figure now was between 600 and 700, fluctuating according to the places available. The number of applicants greatly exceeded the number of vacancies.

Cost of Drugs and Dressings

Dr A. D. D. BROUGHTON asked the Minister what was the present annual cost to the National Health Services of drugs and dressings, and how much of this sum represented the payment of purchase tax.—Mr BEVAN replied. In the twelve months ended May 31, 1950, a total sum of £32,820,258 was paid to general medical practitioners and chemists for the provision of pharmaceutical services. It is estimated that purchase tax accounted for about 1% of this amount.

Homes for Old People in Scotland

In answer to a question Miss M. HERRISON stated that since the passing of the National Assistance Act, 1948, local authorities in Scotland have opened 6 homes for old people, 21 others have been acquired and are at various stages of preparation, while the acquisition of 16 others is being considered.

PARLIAMENTARY MEDICAL GROUP

THE following have been elected officers of the all-party Parliamentary Medical Group: chairman, Lord Haden Guest, vice-chairman and hon. treasurer, Mr Hugh Lanstead, and hon. secretary, Dr Reginald Broughton.

In England Now

A Running Commentary by Peripatetic Correspondents

THE idiom is catching, like chickenpox in a Boy Scout camp, and so is the spelling, so by the time I got thru visiting around in Madison, Peoria, and South Bend, I was feeling right to home. I was relieved to find it was now seldom necessary to explain that a Welshman was not a Limey but a Celt, and a Celt was not a draughty sort of drape tied round the middle of Scotsmen. Confidence was restored and I faced the return from the wide prairie to New York without any of the horrid feeling of being a fugitive from Ellis Island. (Despite the impeccability of my papers and introductions to the Lambs and the Yale Clubs and the Academy of Medicine, that was how I felt a short month before.) I had no hesitation now in giving the visiting fireman routine a twirl, and sent in my card to the chief of a very famous clinic. I need not have worried the first time. Despite the business of the chief, the clinic, and New York in general, my advent appeared to have a top priority rating, an experience which for me was strictly novel.

But this is prolixity—another catching complaint endemic in the Mid-West, in my experience at least. The real point of this faulx is that I going on a ward round with the chief when in came, in a striking white uniform, who but Miss America, or at least if it was not she herself, certainly a top contender for that honor. She was wheeling a gleaming truck with as many gadgets on it as a B28's instrument-panel, topped by a shining dome of chromium the shape of an old-fashioned straw bee-hive. I could not even hazard a guess at what this apparatus was, anyhow it was way out of my league. So playing the local rules I cracked, "What gives with the Wasistmeter Doctor? Is it a super-Geiger counter or is the beautiful lady Flash Gordon's girl friend?" "Oh, that's our clinic Beautician with her portable apparatus." The chief saw this was still double-talk to me, so he explained further. "A long time ago we found that it was impossible to overestimate a woman's pre-occupation with her appearance. She might have no more natural endowment than Ziegfeld would have seen in a Flathead Indian, but that is quite irrelevant to the importance her looks have for her. So it's simple. If they want to go through the motions of beauty-culture why not let them? Even if we think it is screwy, it is dead serious to the women patients. It keeps them contented and occupied, and I'm sure it is therapeutically beneficial." "It is quite useful diagnostically too," he added with a smile. "When they fail to show interest in the Beautician's visit they are very ill indeed. By the way, our Beautician is of course also a trained nurse, so she can adjust her ministrations to ensure that the patient is not overtired by them."

He told me a good deal more of this service the clinic supplied, and though my first reaction was distinctly adverse I was eventually sold on the proposition. After all, why not? Look at the time, energy, and money the ladies spend on their frontage when they are up and around, and it makes them happy. So if they want to buy themselves a hair do and manure in hospital, and if this will hasten their recovery, well good luck to them.

Having lost more than one encounter with examiners, and having seen and heard my most penetrating remarks become the hackneyed howler of the year, I seized with alacrity the chance of becoming an examiner myself. I have, of course, often examined my examiners, and failed them, but only in those precious unreal moments on going to sleep or waking up. The examination I conducted, this time in reality, was on first-aid. I spent the day feverishly reading the manuals and wondering whether the candidates were doing likewise and feeling as nervous as I did. I survived all the vivas but was disappointed that I had no "howler" with which to regale my friends and puff up my ego. The written papers however saved the day. To a question about the treatment of narcotic poisoning one candidate replied, "I would keep him awake by walking him around the room, at the same time slapping the soles of his feet with a wet towel. Also at the same time I would give an emetic

and strong black coffee." If only I had been given this answer in a viva, I might have smiled sweetly in the way examiners do, and said "You are assuming, of course, that you possess two pairs of hands and that the patient possesses two pairs of feet and two stomachs." But more probably I wouldn't have thought of this until the candidate had got away.

WARM AGGLUTININ

I knew a Warm Agglutinin that worked in our laboratory. Who had a most remarkable capacity for oratory. There wasn't any subject that was vague or allegorical. Of which my late acquaintance wouldn't make himself the oracle, No germ of an idea that wouldn't take a rapid root in an Unlimited unstonny ground—my friend the Warm Agglutinin.

The style of his delivery was varied—now declamatory, now logical, now pleading, now amusing, now inflammatory.

He argued about everything, both with and without premises.

He spoke for many hours on the Necessity of Nemesis. When two or three erythrocytes were gathered close together.

He would give them his ideas on the Importance of a Tether.

Or a normoblast, regardless of its patent immaturity. Was treated to a talk on the Illusion of Impurity. He said the Song the Sirens Sang was silver but soluble. —A simple thought which made him wax particularly voluble.

At first these dissertations were diverting and amusing. (We found his manner was, perhaps, a little bit confusing). But slowly we discovered that in any proposition.

He was never for the Government but with the Opposition. The burden of his argument was always so terrific.

We never thought at first that he was wholly non-specific.

For some of us were anti this, and anti that the rest of us, But he was anti-everything, reacting with the best of us. Eternal Anti-Anti, anti-Self, and anti-God, he Was a house divided in itself, an Auto antibody.

While many opportunities were present and get-at-able. We never found a blessed thing with which he was compatible.

We tried to overlook his faults, his lack of specificity, But all was unavailing, he aroused so much publicity. In spite of all our tactfulness and generous expedients. He carried in himself the stuff of civil disobedience. The time arrived at length when we had made our last exploratory.

Attempt to find a little niche for him in our laboratory, And so he had to leave us for the Desert and the Distance. Where, with others like himself, he lives the Image of Existence.

Moral

The Moral of this anecdote you surely haven't missed—When a man is Anti-Everything he Ceases to Exist. As a Wilful Individual Enjoying the Immunity Extended to an Antibody's Work in the Community.

The other morning, one of my peptic ulcer patients came into my surgery and asked for a certificate proving that he really had an ulcer. He explained that he was a member of the same darts team as his butcher, and the butcher had promised that if he could produce medical evidence to show that his ulcer was a reality, he would save him a tender lamb chop whenever there were any. Was I to stand on my dignity and deprive my patient of his vision of a future strewn with succulent lamb chops? Surely not. So I gave him the certificate.

The physician had been discussing the parasites that may cause diarrhoea. "Tell me," he said suddenly to one of the students, "all you know about *Giardia lamblia*." "Well," came the reply, "he was the mayor of New York."

DEAR IF ILLITERATE SIR (June 24).—Peccavi, but how about Cæsar Bell Gall 2, 4. Gall qui ea loca incoherens?

Kingston Victoria Hospital was a hospital of that kind. Public opinion in the district was all but unanimous, and medical opinion entirely unanimous, that this hospital should continue as a small general practitioner unit, but the Minister of Health had refused to take steps to save the hospital. Those who opposed the extinction of the hospital had sought to meet the legitimate concern of the regional hospital board by putting forward a compromise proposal under which the annexe of the Victoria Hospital would be used as the maternity wing. That had been inspected by all the competent people and he was told that a distinguished gynaecologist, who would be in charge of the maternity unit had indicated that in his view these premises would be satisfactory.

Dr CHARLES HILL said that everyone realised the responsibility of the Minister of Health for specialist services but it was in the public interest that there should be an ample provision of general practitioner beds where general practitioners could, in the interests of those patients whose domestic and housing conditions made it necessary, treat their own patients in hospital surroundings.

Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, said the Minister had expressed quite clearly in circulars to the regional hospital boards his desire that general practitioners should not be excluded from small hospitals. He was glad that the amended proposals had been put forward by the regional hospital board taking that point into account. There were bound to arise differences of opinion in a particular area when the hospital board was attempting to secure the best possible use of the accommodation available, but the boards did attempt to reach reasonable conclusions. It was proposed to use the Kingston Victoria Hospital for a most vital purpose. In this area there was an urgent need for more maternity accommodation, and this proposal would affect quite a number of hospitals within the group. It meant for the group as a whole an increase from 81 to 96 maternity beds and from 37 to 40 gynaecological beds. The board in their revised proposals suggested the Surbiton annexe should be used for general medical cases—this would be open to general practitioners—and also that, as far as practicable, there should be posts offered for clinical assistants. But Mr Blenkinsop could not give a guarantee that every practitioner who at present had access to the Kingston Victoria Hospital would automatically secure a clinical assistantship. The desire was that within what was regarded as the proper clinical needs of the area the general practitioner should not be cut off from hospital work. It seemed to the Minister that these modified proposals adequately covered that point.

QUESTION TIME

Medical Services in Malaya

Colonel M STODDART SCOTT asked the Secretary of State for War if additional medical personnel had arrived in Malaya and whether he was satisfied that an adequate service was being provided.—Mr JOHN STRACHEY replied. During my recent visit I naturally looked into this matter very carefully. I think that the supply of specialists in Malaya is completely satisfactory. I found no hospital or unit which felt they were short of specialists, although it is true to say that in some cases they are short of general practitioner establishment. For example, the base hospital at Singapore is short of general practitioners in the sense that they are below establishment. There are quite enough practitioners to cope with the work in hand now, and no man is suffering for lack of general practitioner attention. However, I should like to get the number up a bit towards establishment in case the present wonderful health record of the troops does not continue quite as well. That we are attempting to do. The hon. and gallant gentleman will appreciate the difficulty of getting general practitioners at the moment, but we are sending more out.

Mr STRACHEY added that the health of the troops in the Far Eastern Command was excellent. The medical authorities had assured him that taking one thing with another, the sickness rate was below, rather than above, that of the troops in the United Kingdom.

Advertising of Hospital Staff Vacancies

Sir HUGH LUCAS TOOTH asked the Minister of Health what was the cost, for any convenient area, of advertisement in the press for vacancies on hospital staffs.—Mr A BEVAN replied. The total cost during 1949–50 for all non-teaching hospitals in England and Wales was approximately £500,000.

Sir HUGH LUCAS TOOTH. Does not the Minister think it is a very large sum to pay to newspaper proprietors? I am aware that in many cases these advertisements are mere duplications of one another with perhaps one word changed. Mr BEVAN. I have already called the attention of regional hospital boards to my view that this is an excessive cost but it must be remembered that when the service was built up very large numbers of additional domestic staff were being recruited for the hospitals and that advertisement was necessary for that purpose. For two or three years I was pressed to increase the employment of domestic staff in hospitals and we succeeded in doing this. This was one of the ways of doing it.

Grading of Hospital Medical Officers

Mr G H OLIVER asked the Minister whether he was aware that doctors who were refused consultant status and graded as senior medical officers under the National Health Act had been compelled, in order to obtain posts carrying consultant status, to leave their hospitals and go to others and that the vacancies thus created had been advertised and filled not by doctors graded as senior medical officers but by consultants and whether this practice had his approval.—Mr BEVAN replied. During this transitional period some posts graded for consultants are inevitably held by individuals who have been graded only as senior hospital medical officers. It must, of course, always be open to these officers to seek advertised consultant appointments at their own or other hospitals, if they think they are likely to qualify for them. Mr OLIVER. Does not the Minister appreciate that it causes a great deal of unnecessary hardship if doctors must move to obtain a status to which they ought to have been graded in the first place?—Mr BEVAN. On the contrary, it would cause very considerable hardship if a doctor who had already been graded as a senior medical officer could never have a chance of being regarded as a consultant.

Queen Victoria Hospital, Morecambe

Sir IAN FRASER asked the Minister why this hospital had been converted from a general practitioner hospital to a surgical hospital.—Mr BEVAN replied. I am informed that this was a hospital where specialist work was done by general practitioners supported by visiting specialists. The change made by the regional board has been to give specialists charge of this work.

Dental Students

In answer to a question Mr BEVAN stated that the annual pre-war intake of students in dental schools in the United Kingdom was about 400. The corresponding figure now was between 600 and 700, fluctuating according to the places available. The number of applicants greatly exceeded the number of vacancies.

Cost of Drugs and Dressings

Dr A D D BROUGHTON asked the Minister what was the present annual cost to the National Health Services of drugs and dressings and how much of this sum represented the payment of purchase tax.—Mr BEVAN replied. In the twelve months ended May 31, 1950, a total sum of £32,820,211 was paid to general medical practitioners and chemists for the provision of pharmaceutical services. It is estimated that purchase tax accounted for about 1% of this amount.

Homes for Old People in Scotland

In answer to a question Miss M HERBISON stated that since the passing of the National Assistance Act, 1948, local authorities in Scotland have opened 6 homes for old people. 21 others have been acquired and are at various stages of preparation, while the acquisition of 16 others is being considered.

PARLIAMENTARY MEDICAL GROUP

The following have been elected officers of the all-part Parliamentary Medical Group: chairman, Lord Hader; Guest, vice-chairman and hon. treasurer, Mr Hugh Linstead; and hon. secretary, Dr Reginald Broughton.

Letters to the Editor

1

RESEARCH UNDER THE NATIONAL HEALTH SERVICE

SIR,—In reply to a specific inquiry from our hospital management committee, the Minister has informed us that it would not be practicable to budget a set amount each year for medical research. The Minister has recently stipulated that all research work must be reported to him for reference to the Medical Research Council. A hospital management committee is powerless to act unless an item has been budgeted in advance and therefore there must be a delay of approximately six to eighteen months before a project can be financed. Thus, of course, effectively excludes hospital management committees from assisting in medical research projects.

It is true that medical research can be financed from the free moneys, but the amount available to this hospital amounts to a few hundred pounds only per annum and is barely sufficient to cover the amenities for patients. A direct approach can, of course, be made to the Medical Research Council but many would feel diffident about asking for a small sum to cover a piece of apparatus or extra clerical assistance.

The district hospitals of this country represent a vast reservoir of clinical material for simple and yet very useful medical research. Formerly, the Middlesex County Council gave willing support to small research schemes, and a lively interest in medical research developed in their hospitals. If hospital management committees were allowed to budget for small items of medical research, many valuable growing points would emerge which could then be nurtured by the Medical Research Council.

Central Middlesex Hospital,

F. AVERY JONES

EPHEDRINE AND RHEUMATIC DISEASES

SIR,—In January, 1946, a patient of mine, aged 73, was confined to bed for 10 days with acute diffuse fibrositis of the back and thighs. Tender rheumatic nodules were present, and movement in bed was difficult and painful. She then developed urticaria, which was treated with ephedrine gr $1\frac{1}{2}$, followed by gr $\frac{1}{2}$ at 2 hourly intervals. Within 6 hours the skin had cleared and so also had the fibrositis. She became entirely free from pain, all local tenderness had gone, and she got up feeling immensely pleased with herself. Three days later she undertook the exacting journey to Ireland with no ill effect, and she had no return of her trouble during the rest of that year.

Spellbound by this unexpected result and basing my conclusions on the known properties of ephedrine, I applied the same treatment to every case of fibrositis and rheumatoid arthritis which came my way during the next few months. My results were inconclusive, and in those cases in which the treatment appeared to be successful I did not discount the possibility of spontaneous remission. Finally, as I contemplated an asthmatic patient in whom the asthma was relieved by ephedrine while her fibrositis and rheumatoid arthritis remained unchanged, I abandoned my activities with much disappointment.

A new light is thrown on my findings, however, by the theory that circulatory adrenaline stimulates the secretion of a humoral substance by the cells of the anterior hypothalamus, which stimulates the production of adrenocorticotrophic hormone (A.C.T.H.), and that the secretion and effect thereof is related to the hormone adaptive mechanism of the whole organism. It would appear that in my cases the ephedrine acted in the same manner as circulatory adrenaline and stimulated the production of A.C.T.H. via the anterior hypothalamus, and that the presence or absence of hormone balance and

adaptation accounted for the contradictory successes and failures in the cases so treated.

I certainly feel encouraged to resume treatment of the rheumatic diseases with ephedrine, with the help of my past experience of the dosage and response. If no result is obtained within 24 hours it is unlikely that any will be obtained, but if there is any initial response it is worth continuing until that response is complete. The initial dose must be high—not less than gr $1\frac{1}{2}$ —and use of the drug and dosage must be related to the general make up of the patient and the likelihood of adverse side effects. If there has been previous stress it might be well to begin treatment with absolute rest and a general toning down of the patient, and then, when this has been accomplished, to hit and hit hard with ephedrine. In cases where the adaptive hormone mechanism is sufficiently intact, one may hope to obtain a complete remission of symptoms.

Present knowledge of the importance of the adaptive hormone system explains the failures encountered with this method of treatment. Ephedrine is cheap and readily accessible. A single day's treatment will show whether it will succeed or not. If it does succeed, the effect is dramatic, both in fibrositis and in rheumatoid arthritis. If it fails no harm is done. Bearing in mind the fluctuations in the hormone mechanism, it might be worth while repeating treatment at intervals of 2-3 months in cases which have failed to respond.

London S W 3

WINIFRED REDMOND

THE G.P.'s EQUIPMENT

SIR,—Doubtless, as Dr. Davies says in his letter of June 17, Professor Ryle found a stethoscope and a percussion hammer adequate. Unfortunately, my experience as a general practitioner has several times borne in on me the sparseness of Professor Ryle's equipment when faced with a ripe abscess, an intravenous injection, or a difficult forceps delivery. More important to-day patients attending the general practitioner could benefit from improved diagnostic methods (simple radiological and pathological investigations), therapeutic devices (physiotherapy, frequent injections), and similar advances in medical science which are not beyond the skill of the G.P. but simply beyond his capital resources.

Nor is the present day general practitioner well equipped in other spheres. Nobody questions his ability to carry on general practice as his grandfather and his grandfather did in years gone by, but today there is far more to know about in medicine, and far more to know about it. As a result, even in consultant ranks, the general physician and the general surgeon are giving way to teams of doctors working together to produce maximum benefit for the patient. How can the individual G.P. hope to keep his head above water when the tide of learning is flowing daily faster and higher?

Many will agree that to bring all the knowledge and experience of current medical science to the point where it is most useful—that point of initial contact between the health service and the bulk of its users which is the general practitioner—needs more than the capabilities of one man. It demands a team of general practitioners working harmoniously together in one spot, equipped with the instruments and ancillary staff necessary to make use of our increased and increasing understanding of the maintenance of health and the fight against disease.

Teams of doctors mean group practice. Adequate equipment in suitable buildings means health centres, and many of us wonder whether doctors can work as a team while they are also working in keen financial competition against each other.

This is a simple and unoriginal sequence of argument. It has nothing to do with Socialism. The virtue of

...ing technical progress to liberal humanitarianism is of the prerogative of Socialists except in so far as it is abandoned by anti-Socialists

London SW 17

DAVID KERP

KERNICTERUS AND PREMATURITY

SIR,—I was very interested to learn from their article last week that Dr Aidin, Dr Corner, and Dr Tovey have found that premature babies as well as those with hemolytic disease of the newborn are particularly liable to develop kernicterus. A similar association has been noticed at the Children's Hospital Birmingham, and during the five years 1944-49, of 43 cases of kernicterus which came to autopsy 9 were unassociated with Rh or with ABO incompatibility (We are grateful to Dr A. E. Mourant for his help with the serology and genotyping.) These 9 cases of kernicterus were all premature babies. The first case to be noted was reported by Baar¹, this and the second case were those mentioned by Parsons². Zuelzer³ has more recently drawn attention to the frequency with which kernicterus occurs in premature.

Kernicterus would therefore appear to be a disease associated both with hemolytic disease of the newborn and with prematurity as Aidin, Corner and Tovey point out and it would seem reasonable to presume that in both cases it has a similar aetiology. One of the most striking features of kernicterus, both in erythroblastosis and in prematures is that the babies unlike those with an intracranial birth injury, show no evidence of a cerebral lesion immediately after delivery or during the next 24-48 hours, but during the third or fourth day or perhaps a day or two later in prematures opisthotonos and rigidity suddenly supervene. In our last two cases of kernicterus associated with prematurity the diagnosis was suggested ante mortem by Dr E. Howarth, pediatric registrar at the Sorrento Premature Babies Unit.

Just as there is a physiological hyperbilirubinemia postnatally and a physiological hypoprothrombinemia, there is also a physiological hypoglycemia⁴ which is most marked in premature babies⁵. Hypoglycemia is known to result in damage to the nerve-cells and it seems to me reasonable to postulate that the liver in normal babies contains a supply of glycogen sufficient to last until oral feeding is initiated, but that where liver function is impaired, as in erythroblastosis, or where liver function is immature, as in premature infants, a dangerous hypoglycemia might arise and result in cerebral damage. Hyperbilirubinemia being common to both hemolytic disease of the newborn and to prematures the damaged cells would take up the pigment and nuclear jaundice would be manifest at autopsy.

After formulating this hypothesis, our next case of erythroblastosis with kernicterus had on the seventh day of life (the day before death) as anticipated, a low blood sugar level—namely 19 mg per 100 ml.

In the next case we were able to follow the blood-sugar levels from birth. There was a fall to 20 mg per 100 ml twelve hours after delivery but thereafter the level rose gradually and when kernicterus became clinically apparent on the third day the blood sugar level had risen to 68 mg per 100 ml. Death occurred thirty-six hours later.

The next case of erythroblastosis was given 20 ml of 50% glucose intravenously twelve hours after delivery, when the blood sugar was only 25 mg per 100 ml. Twenty-two hours later the level had fallen again, to 34 mg per 100 ml, but by giving 20% glucose orally four hourly a further fall was prevented and the baby has no clinical evidence of kernicterus.

In three subsequent cases the blood sugar has shown no dramatic fall at any time and none have developed kernicterus.

In premature babies, as Norval⁵ has shown there may be marked hypoglycemia within twelve hours of delivery. We have confirmed these findings. It would appear that in the fetus in utero there may be a hyperinsulinemia so that as quickly as glucose passes through the placenta it is utilised or stored by the fetus, if the baby is born prematurely the hyperinsulinemia causes a rapid and immediate fall in the blood sugar level. This hyperinsulinemia may persist as long as there is any hemopoietic activity in the liver—this is purely conjectural—but if this is so it would explain why hyperglycemia and kernicterus are particularly liable to occur both in prematures and in hemolytic disease of the newborn. In a normal full term baby the blood-sugar level does not fall dramatically.

I cannot state that hypoglycemia is a *sine qua non* of kernicterus but there is presumptive evidence that it may be so, and that the early administration of glucose intravenously may protect the nerve-cells from damage. If hypoglycemia itself is not the initiating factor, I feel that it is in some such mechanism that we shall find the clue to kernicterus. Further work is being pursued on these lines and I would like to thank Dr E. Howarth, Dr Barbara Davies, and Miss S. A. Burnett for their help and co-operation.

Department of Pediatrics and Child Health University of Birmingham

JOHN GERRARD

LEGAL LIABILITY OF HOSPITAL DOCTORS

SIR.—May I amplify the sage advice in Mr McFurland's letter of May 27?

Not only may a hospital authority bring in the doctor concerned as a third party when sued but a patient who claims damages for alleged negligent treatment will probably sue the doctor concurrently, as a plaintiff gains certain technical advantage in having him as a defendant. The Ministry of Health have directed that hospital authorities should not undertake the defence of hospital doctors who may be thus sued. Moreover, the Ministry have also directed hospital authorities, if it is sought to make them liable for the negligent acts of a doctor, to take such steps as are open to them under the Law Reform (Married Women & Tortfeasors) Act 1935, to obtain from the doctor a contribution, which may amount to complete indemnity in respect of damages that may be recovered.

The existing law as regards liability of a hospital authority for the negligent acts of the members of the hospital staff may be fairly summarised as follows. The hospital authority

1 Is not responsible for the negligent acts of a consulting surgeon or physician.

2 Is (probably) not responsible for the negligent acts of a house physician or house-surgeon provided due care and skill has been exercised in his selection for the appointment but recent decided cases have left this question open and the present legal position is by no means free from doubt.

3 Is normally responsible for the negligent acts in the course of their employment of medically unqualified members of the hospital staff—e.g. nurses and radiographers.

It is therefore essential that every doctor, whether he be in hospital or other salaried practice, whole time or part time, should be a member of one of the recognised protection societies.

Furthermore although the Limitation Act, 1939, normally requires such a claim to be made within six years of the date when the cause of action accrued (which in actions founded on negligence will usually be the date of the negligent act or last negligent act), in those cases where damage from the negligent act does not arise until some time afterwards, time begins to run from the date of damage. This is of particular importance to doctors since damage resulting from alleged negligent treatment may not become apparent

Letters to the Editor

RESEARCH UNDER THE NATIONAL HEALTH SERVICE

SIR,—In reply to a specific inquiry from our hospital management committee, the Minister has informed us that it would not be practicable to budget a set amount each year for medical research. The Minister has recently stipulated that all research work must be reported to him for reference to the Medical Research Council. A hospital management committee is powerless to act unless an item has been budgeted in advance and therefore there must be a delay of approximately six to eighteen months before a project can be financed. This, of course, effectively excludes hospital management committees from assisting in medical research projects.

It is true that medical research can be financed from the free moneys, but the amount available to this hospital amounts to a few hundred pounds only per annum and is barely sufficient to cover the amenities for patients. A direct approach can, of course, be made to the Medical Research Council but many would feel diffident about asking for a small sum to cover a piece of apparatus or extra clerical assistance.

The district hospitals of this country represent a vast reservoir of clinical material for simple and yet very useful medical research. Formerly, the Middlesex County Council gave willing support to small research schemes, and a lively interest in medical research developed in their hospitals. If hospital management committees were allowed to budget for small items of medical research, many valuable growing points would emerge which could then be nurtured by the Medical Research Council.

EPHEDRINE AND RHEUMATIC DISEASES

SIR,—In January, 1946, a patient of mine, aged 73, was confined to bed for 10 days with acute diffuse fibrositis of the back and thighs. Tender rheumatic nodules were present, and movement in bed was difficult and painful. She then developed urticaria, which was treated with ephedrine gr $1\frac{1}{2}$, followed by gr $\frac{1}{2}$, at 2 hourly intervals. Within 6 hours the skin had cleared and so also had the fibrositis. She became entirely free from pain, all local tenderness had gone, and she got up feeling immensely pleased with herself. Three days later she undertook the exacting journey to Ireland with no ill effect, and she had no return of her trouble during the rest of that year.

Spellbound by this unexpected result and basing my conclusions on the known properties of ephedrine, I applied the same treatment to every case of fibrositis and rheumatoid arthritis which came my way during the next few months. My results were inconclusive, and in those cases in which the treatment appeared to be successful I did not discount the possibility of spontaneous remission. Finally, as I contemplated an asthmatic patient in whom the asthma was relieved by ephedrine while her fibrositis and rheumatoid arthritis remained unchanged, I abandoned my activities with much disappointment.

A new light is thrown on my findings, however, by the theory that circulatory adrenaline stimulates the secretion of a humoral substance by the cells of the anterior hypothalamus, which stimulates the production of adrenocorticotrophic hormone (A.C.T.H.), and that the secretion and effect thereof is related to the hormone adaptive mechanism of the whole organism. It would appear that in my cases the ephedrine acted in the same manner as circulatory adrenaline and stimulated the production of A.C.T.H. via the anterior hypothalamus, and that the presence or absence of hormone balance and

adaptation accounted for the contradictory successes and failures in the cases so treated.

I certainly feel encouraged to resume treatment of the rheumatic diseases with ephedrine, with the help of my past experience of the dosage and response. If no result is obtained within 24 hours it is unlikely that any will be obtained, but if there is any initial response it is worth continuing until that response is complete. The initial dose must be high—not less than gr $1\frac{1}{2}$ —and use of the drug and dosage must be related to the general make-up of the patient and the likelihood of adverse side effects. If there has been previous stress it might be well to begin treatment with absolute rest and a general toning down of the patient, and then, when this has been accomplished, to hit and hit hard with ephedrine. In cases where the adaptive hormone mechanism is sufficiently intact, one may hope to obtain a complete remission of symptoms.

Present knowledge of the importance of the adaptive hormone system explains the failures encountered with this method of treatment. Ephedrine is cheap and readily accessible. A single day's treatment will show whether it will succeed or not. If it does succeed, the effect is dramatic, both in fibrositis and in rheumatoid arthritis. If it fails no harm is done. Bearing in mind the fluctuations in the hormone mechanism, it might be worth while repeating treatment at intervals of 2-3 months in cases which have failed to respond.

WINIFRED REDMOND

THE G.P.'s EQUIPMENT

SIR,—Doubtless, as Dr Davies says in his letter of June 17, Professor Ryle found a stethoscope and a percussion hammer adequate. Unfortunately, in experience as a general practitioner has several times borne in on me the sparseness of Professor Ryle's equipment when faced with a ripe abscess, an intravenous injection, or a difficult forceps delivery. More important today, patients attending the general practitioner could benefit from improved diagnostic methods (simple radiological and pathological investigations), therapeutic devices (physiotherapy, frequent injections), and similar advances in medical science which are not beyond the skill of the G.P. but simply beyond his capital resources.

Nor is the present day general practitioner well equipped in other spheres. Nobody questions his ability to carry on general practice as his grandfather and his grandfather did in years gone by, but today there is far more to know about in medicine, and far more to know about it. As a result, even in consultant ranks, the general physician and the general surgeon are giving way to teams of doctors working together to produce maximum benefit for the patient. How can the individual G.P. hope to keep his head above water when the tide of learning is flowing daily faster and higher?

Many will agree that to bring all the knowledge and experience of current medical science to the point where it is most useful—that point of initial contact between the health service and the bulk of its users which is the general practitioner—needs more than the capabilities of one man. It demands a team of general practitioners working harmoniously together in one spot, equipped with the instruments and ancillary staff necessary to make use of our increased and increasing understanding of the maintenance of health and the fight against disease.

Teams of doctors mean group practice. Adequate equipment in suitable buildings means health centres, and many of us wonder whether doctors can work as a team while they are also working in keen financial competition against each other.

This is a simple and unoriginal sequence of argument. It has nothing to do with Socialism. The virtue of

ing technical progress to liberal humanitarianism is the prerogative of Socialists, except in so far as it is abandoned by anti Socialists

London SW 17

DAVID KEPR

KERNICTERUS AND PREMATURITY

SIR,—I was very interested to learn from their article last week that Dr Aidin, Dr Corner, and Dr Tovey have found that premature babies as well as those with hemolytic disease of the newborn are particularly liable to develop kernicterus. A similar association has been noticed at the Children's Hospital, Birmingham and during the five years 1944-49, of 43 cases of kernicterus which came to autopsy 9 were unassociated with Rh or with ABO incompatibility. (We are grateful to Dr A. E. Lourant for his help with the serology and genotyping.) These 9 cases of kernicterus were all premature babies. The first case to be noted was reported by Baar¹, and the second case were those mentioned by Parsons². Zuelzer³ has more recently drawn attention to the frequency with which kernicterus occurs in prematures.

Kernicterus would therefore appear to be a disease associated both with hemolytic disease of the newborn and with prematurity, as Aidin, Corner, and Tovey point out, and it would seem reasonable to presume that in both cases it has a similar etiology. One of the most striking features of kernicterus, both in erythroblastosis and in prematures, is that the babies, unlike those with an intracranial birth injury, show no evidence of a cerebral lesion immediately after delivery or during the next 24-48 hours, but during the third or fourth day, or perhaps a day or two later in prematures opisthotonos and rigidity suddenly supervene. In our last two cases of kernicterus associated with prematurity the diagnosis was suggested ante mortem by Dr E. Howarth, pediatric registrar at the Sorrento Premature Babies Unit.

Just as there is a physiological hyperbilirubinemia postnatally and a physiological hypoprothrombinemia, there is also a physiological hypoglycemia⁴ which is most marked in premature babies⁵. Hypoglycemia is known to result in damage to the nerve cells and it seems to me reasonable to postulate that the liver in normal babies contains a supply of glycogen sufficient to last until oral feeding is initiated, but that where liver function is impaired, as in erythroblastosis, or where liver function is immature, as in premature infants, a dangerous hypoglycemia might arise and result in cerebral damage. Hyperbilirubinemia being common to both hemolytic disease of the newborn and to prematures the damaged cells would take up the pigment and nuclear jaundice would be manifest at autopsy.

After formulating this hypothesis, our next case of erythroblastosis with kernicterus had, on the seventh day of life (the day before death) as anticipated, a low blood sugar level—namely, 19 mg per 100 ml.

In the next case we were able to follow the blood sugar levels from birth. There was a fall to 20 mg per 100 ml twelve hours after delivery but thereafter the level rose gradually and when kernicterus became clinically apparent on the third day the blood sugar level had risen to 68 mg per 100 ml. death occurred thirty six hours later.

The next case of erythroblastosis was given 20 ml of 50% glucose intravenously twelve hours after delivery, when the blood sugar was only 25 mg per 100 ml. twenty-two hours later the level had fallen again, to 34 mg per 100 ml, but by giving 20% glucose orally four hourly a further fall was prevented and the baby has no clinical evidence of kernicterus.

In three subsequent cases the blood sugar has shown no dramatic fall at any time and none have developed kernicterus.

¹ Baar H S. *Aust'r med Bull* 1945 1 special issue

² Parsons L G. *Lancet* 1947 1 515

³ Zuelzer W F. *Pediatrics*, 1949 4 289

⁴ Norval M. A. Kennedy R L J. Berkson J. *J Pediatr* 1949 34 342

⁵ Norval, M.A. *Ibid* 1950 36 177

In premature babies, as Norval⁵ has shown there may be marked hypoglycemia within twelve hours of delivery, we have confirmed these findings. It would appear that in the fetus in utero there may be a hyperinsulinemia so that as quickly as glucose passes through the placenta it is utilised or stored by the fetus, if the baby is born prematurely the hyperinsulinemia causes a rapid and immediate fall in the blood sugar level. This hyperinsulinemia may persist as long as there is any hemopoietic activity in the liver—this is purely conjectural—but if this is so it would explain why hyperglycemia and kernicterus are particularly liable to occur both in prematures and in hemolytic disease of the newborn. In a normal full term baby the blood-sugar level does not fall dramatically.

I cannot state that hypoglycemia is a sine qua non of kernicterus, but there is presumptive evidence that it may be so, and that the early administration of glucose intravenously may protect the nerve cells from damage. If hypoglycemia itself is not the initiating factor, I feel that it is in some such mechanism that we shall find the clue to kernicterus. Further work is being pursued on these lines, and I would like to thank Dr E. Howarth, Dr Barbara Davies, and Miss S. A. Barnett for their help and co-operation.

JOHN GEPPARD

LEGAL LIABILITY OF HOSPITAL DOCTORS

SIR.—May I amplify the sage advice in Mr McFarland's letter of May 27?

Not only may a hospital authority bring in the doctor concerned as a third party when sued but a patient who claims damages for alleged negligent treatment will probably sue the doctor concurrently, as a plaintiff gains certain technical advantage in having him as a defendant. The Ministry of Health have directed that hospital authorities should not undertake the defence of hospital doctors who may be thus sued. Moreover, the Ministry have also directed hospital authorities, if it is sought to make them liable for the negligent acts of a doctor, to take such steps as are open to them under the Law Reform (Married Women & Tortfeasors) Act, 1935, to obtain from the doctor a contribution, which may amount to complete indemnity in respect of damages that may be recovered.

The existing law as regards liability of a hospital authority for the negligent acts of the members of the hospital staff may be fairly summarised as follows. The hospital authority

1 Is not responsible for the negligent acts of a consulting surgeon or physician

2 Is (probably) not responsible for the negligent acts of a house physician or house-surgeon provided due care and skill has been exercised in his selection for the appointment, but recently decided cases have left this question open and the present legal position is by no means free from doubt.

3 Is normally responsible for the negligent acts in the course of their employment of medically unqualified members of the hospital staff—e.g., nurses and radiographers.

It is therefore essential that every doctor, whether he be in hospital or other salaried practice, whole time or part time, should be a member of one of the recognised protection societies.

Furthermore, although the Limitation Act, 1939, normally requires such a claim to be made within six years of the date when the cause of action accrued (which in actions founded on negligence will usually be the date of the negligent act or last negligent act), in those cases where damage from the negligent act does not arise until some time afterwards, time begins to run from the date of damage. This is of particular importance to doctors since damage resulting from alleged negligent treatment may not become apparent

until long after such treatment was given. Also, if the plaintiff is under a "legal disability" (e.g., infancy or lunacy) at the date when the cause of action accrues, the six years begin to run from the time when (a) the legal disability ceases, or (b) the injured party dies, whichever occurs first. Continuity of protection is therefore equally essential for retired doctors and for doctors who leave this country but continue practice overseas, including visitors from overseas who come here for a period of postgraduate work.

The Medical Protection Society offers such continuity of protection not only to doctors on the permanent British Medical Register, but to those who are temporarily registered here whilst doing postgraduate work under the Medical Practitioners and Pharmacists Act, 1947, for a small compound (not "combined" as stated in Mr McFarland's letter) subscription, when they leave the British Isles and do not elect to continue membership either as retired doctors or under the overseas scheme.

THE PATHOLOGY OF VIRUS INFECTIONS RÔLE OF THE VIRUS BODIES

SIR,—I have read the contribution of Prof F W Burnet to your issue of June 10 on the mode of action of viruses, and have also had the pleasure of listening to his Croonian lecture at the Royal Society on June 14 with admiration for the initiative, drive, chemical ingenuity, and daring with which he has assailed the problem of the mode of action of viruses—one of the most difficult of the problems of pathology still unsolved.

But I must disagree with him entirely when he states that there is no clear evidence of any toxic products of the virus itself. Observations made not only on laboratory animals, but also on man, and spread over many years, have convinced me that, as in the case of many pathogenic bacteria including the meningococcus, the major portion of the toxic factor is contained within the virus units themselves—the elementary bodies or EBS. The evidence for this view is described in a lecture which you published on May 8, 1948, under the title "Is rheumatism a virus disease?" As regards the substance in immune serum referred to by Burnet and others as "antibody," from experiments with vaccinia virus employing the ordinary lysin technique, contact in vitro for 30 minutes at 37°C in small tubes, and the rabbit's skin as reagent, it seemed likely that a part of this antibody may be thermostable lysin. But in addition there are the usual specific antibodies so well known in the case of bacteria, and of these the flocculating antibodies are the most easily perceived.

EXPENSIVE HYGIENE

SIR,—The rather costly experience of your peripatetic correspondent (June 17) in a public lavatory in the West End of London, where she and her friend were charged 8d for using a convenience and subsequently washing their hands, prompts me to remind your readers that in the Borough of St Marylebone there is not only free urinal accommodation but free washing facilities in all the public conveniences. The object of the free washing service is to encourage personal hygiene and to prevent the spread of disease. It forms part of a clean-food campaign in the borough, now crystallised in the recently established St Marylebone Clean Food Association. This association has a code of practice to be observed by all engaged in the handling of food for sale to the public.

Town Hall St Marylebone

H A BULMAN
Medical Officer of Health

TRAVELLING EXHIBITIONS ON CLEANLINESS

SIR,—The proposed travelling exhibitions briefly described in your issue of June 24 are to be welcomed.

Recently, with the very willing assistance of the C O I, we showed the film *Another Case of Poison* throughout the area. In conjunction with this, we exhibited in canteens at pits and factories the Central Council for Health Education's stand on Food and Drink Infections, as we felt that this might be a good method of reaching the public through the worker of the family. The film shows were primarily intended for food handlers.

Over 5000 pieces of literature were taken from the stand during a fortnight's tour—which can, I think, be regarded as a good "take". No doubt the short stay of the stand (which imposed a severe burden on transport, owing to its bulk) at each place, plus the fact that the stand had not previously been exhibited by the local health authority in such places, created an atmosphere of novelty which contributed to the results, but certainly this method of approaching the public is very hopeful, provided it is not overdone.

Not being a local health authority, we could only obtain the stand on short term loan, and it appears that the number apportioned by the Central Council to this type of work is inadequate. Likewise the stand could be considerably reduced in size without impairing its utility, so that it could be transported by a small van, and not require a lorry.

As regards the film itself, our experience suggests that a longer programme is usually desirable. We felt that shortness would commend itself to employers in releasing staff, but in some cases there was the feeling that it was so short that it was not worth going to.

Chester le Street,
co Durham

A FORSTER
Medical Officer of Health

DOSAGE OF DIAMINO-DIPHENYL SULPHONE

SIR,—I wish to add a note to my article on the treatment of leprosy with diamino diphenyl sulphone (D A D P S) by mouth, which appeared in your issue of Jan 28.

In the article I outlined treatment with a dosage rising from 100 mg a day to 300 mg a day, the latter dose being attained only in the fifth week. This dosage is usually well tolerated by our African patients here, but I suggested that it might be unnecessarily high and that a lower dose or less frequent administration might be found preferable.

Studies carried out here now show that a lower dosage is effective, and similar findings have been made elsewhere.¹ It is found here that a weekly dosage of 700 mg (1 tablet of 100 mg a day) is usually enough to produce a good clinical and bacteriological response, but we like to give more than this. At present I am treating patients on four different dosage systems

Dose (mg) and frequency	Weekly total G
(1) 300 six days a week	18
(2) 300 alternate days excluding Sundays	9
(3) 200, six days a week	12
(4) 500, twice a week	10

There is so far no significant difference in the response to these differing dosages in lepromatous cases, but in tuberculoid cases daily administration appears to produce a more rapid response. The lower dosage is somewhat more easily tolerated, though little serious trouble has been encountered on the higher dosage.

Since these studies were undertaken, three different workers in different parts of India have written to me saying that Indians appear to tolerate D A D P S less readily than Africans, and that the dosage I originally recommended (300 mg each day of the week) is too high.

¹ Moleworth, B D, Narayanaswami P S, *Int J Leprosy*, 1948, 17, 197. Muir E. Personal communication.

For them, progressive anaemia is not uncommon. It is good to be able to assure these workers, and any others who may be experiencing this difficulty, that the dosage of DADPS can be considerably reduced with little or no loss of therapeutic efficacy. Moreover, the lower dosage still further reduces the already very low cost of this form of sulphone treatment.

I would point out once more the vital necessity of a low induction of treatment with DADPS, even with these lower dosage levels. The standard dose should not be attained for at least one month, and perhaps not for six weeks or more.

JOHN LOWE

CANCER OF THE UTERINE CERVIX

SIR,—In your annotation of June 3 you say "The Cancer Act of 1939 included provision for complete registration of cancer, one of the objects being the statistical comparison of methods of treatment. This part of the Act still stands, and one or two regions have started complete registration."

This provision was made under section 1 of the Cancer Act which was, in fact, repealed by the National Health Service Act, 1946.

The Minister's intention that cancer registration should extend to the whole country does, of course, still stand, and the importance of the collection of adequate records was emphasised in a memorandum sent by him to hospital boards in July, 1949. The General Register Office is now responsible for the central collection of statistics relating to cancer registration and treatment, and will shortly be publishing a report on registration in the early post war years.

General Register Office,
Somerset House London WC2

ANTI-HISTAMINE DRUGS IN PARKINSONISM

SIR,—In the following case of parkinsonism I obtained good results with 'Phenergan' after getting none with 'Neoantegan'.

A married woman, aged 46, consulted her doctor four years earlier because of continuous tremor of the hands. Parkinsonism was diagnosed and the patient was treated with scopolamine for a long time without reaping any benefit. Later she was treated with 'Parpanit' in full dosage and with intrathecal magnesium sulphate with similar results. Atropine which was also tried, slightly reduced the tremor. There was no history of syphilis, gonorrhoea, or trauma. The Wassermann reaction was negative in blood and cerebrospinal fluid.

On examination the patient had tremor of her hands and left leg while at rest. Her shoulder muscles were somewhat rigid, her movements were abnormally slow, and she did not swing her arms normally in walking. She had a dull, sad, puzzled expression on her face. She was uneasy while sitting and kept changing her position. She complained of a burning sensation in the lumbar region, in her palms, and elsewhere in her body, of pains in the lumbar region, and of sweating even while sitting still. Her tendon reflexes were exaggerated and her plantar reflexes normal.

Treatment—After treating her unsuccessfully with neoantegan I tried phenergan 0.15 g six times a day. At first she complained of muscular spasms, but these passed off in two or three days, and there was a great reduction in tremor and rigidity while the phenergan was continued, whereas if it was withheld for twenty-four hours these symptoms returned.

'Diparcol' was also used in this case, but it did not influence the tremor and rigidity. 'Benadryl' relieved muscle spasms, but it had no effect on the tremor.

The full dosage of phenergan should be reached gradually, if it is given at the start of treatment it is apt to cause spasm. The usual dosage is 0.2–0.4 g daily. In oculogyric crises a single intravenous injection of 0.1 g, given slowly, may be effective.

M HULUSI DOSDOGRU

DAIRY-GOAT'S MILK

SIR,—I was interested by Mr Harris's letter last week. As to the merits of goat's milk I express no opinion, except to agree that if obtained from a well tended herd it is pleasant and indeed hardly to be distinguished from cow's milk. But would Mr Harris care to quote the evidence on which, he bases his statement that "over one third of our dairy cows are tuberculous"? Even if he really means "give a positive reaction to tuberculin," which is very far from being tuberculous in the sense of having any tuberculous lesion, open or otherwise, the proportion stated seems astonishingly large and indeed difficult to believe.

14.5	62	—	—	110	—	—
15.5	65	—	—	122½	—	—

* The averages at the stated age intervals are obtained by simple linear interpolation of the crude data.

with pre-war averages from 5 to 15 years of age. The report indicates that for both boys and girls, and at every age, there have been increases in both height and weight over the past ten years. The average increase, for both boys and girls, in height is about 1.3%, and in weight 2.2% of the 1938 level. For example, boys and girls aged 10 have in the past decade increased their average weight by 1¾ lb and their average height by ¾ in. As in 1938, boys are heavier and taller than girls up to the age of 11 years, while from 11 to 14 years of age the reverse applies. The superiority

¹ Report on the Heights and Weights of School Pupils in the County of London in 1949. By Sir ALLEN DALEY M.D. F.R.C.P. School medical officer London County Council. The report will be obtainable from Staples Press Ltd 14 Great Smith Street S.W.1 either direct or through a bookseller. Pp 26 1s.

in the weight of girls over boys lingers on to the 16th year, but with height the superiority of girls ends at 14 years, and for ages 15 and 16 years boys resume their lead over girls. With regard to the relationship of weight to height generally, a striking feature of the changes in the averages over the past ten years is the fact that the change in weight has been proportionate to the change in height so as to leave the ratio of weight to height in each age-group almost unchanged. The fact that bone and flesh have kept pace with each other, despite substantial changes in the absolute values of height and weight, suggests that with improved nutrition in school children, nature has maintained her own balance, that children of today are not merely heavier or merely taller than were their parents, but are of altogether greater physique. It is as though by pre-war scales of growth the post-war children were 3 months older than indicated by their year of birth.

As was known before the war, there are differences between districts of London. There is a tendency for the averages for both height and weight to be greater south of the Thames than on the north side of the river. Although the greatest improvement has been in those districts which were above average in 1938, there has been a definite improvement in the worst areas where war conditions produced greatest retardation and where it was known that progress would be most difficult to achieve.

Poliomyelitis in England and Wales

In the 24th week, ended June 17, there were 93 (79) notifications of poliomyelitis—77 (61) paralytic cases and 16 (18) non-paralytic cases. Figures for the previous week are shown in parentheses. Although the upward trend continues, the recent rise is less steep than that which preceded the 23rd week. The main concentration of cases continues to be in the Midlands, and 28 (20) of the 77 paralytic cases were notified in Birmingham, where there has been a total of 65 cases in the past four weeks. When this foyer in Warwickshire is discounted, the figures for the rest of the country do not yet suggest the beginning of a large rise.

GARROW HELEN M.B. St. And. D.P.H. senior asst. M.O. Middlesex health dept.
KERSHAW J. B. M.B. Lond. D.P.H. senior asst. M.O. Middlesex health dept.
MATSON NEILL D. F.R.C.S.E. D.L.O. consultant E.N.T. surgeon Mid Glamorgan hospital management committee group.
WILLIAMS R. M. M.B. Lond. M.R.C.O.G. consultant obstetrician and gynecologist Glantawe Hospital management committee group.

Births, Marriages, and Deaths

BIRTHS

DENNY—On June 18 in Plymouth the wife of Surgeon Commander G. C. Denny R.N.—a son.
DUNLOP—On June 14 in London the wife of Dr. Eric Dunlop—a son.
HEWITT—On June 17 the wife of Dr. Patrick Hewitt of Bishop's Stortford—a daughter.

MARRIAGES

GRIFFITHS—SMITH—On June 17 in London Glyn Griffiths M.B. to Barbara Smith.
JAGGER—JARRATT—On June 17 at Bridlington Derek Bourne Jagger M.B.F. M.B. major R.A.M.C. to Pamela Marjorie Jarratt.

DEATHS

DAWSON—On June 17 at Swindon William Richard Dawson O.B.E. M.D. Dubl. F.R.C.P.I. aged 85.
FIELDING—On June 19 Charles Henry Fielding M.R.C.S. Lieut. colonel I.M.S. ret'd.
FITCH—On June 17 Edward Louis Vincent Fitch M.R.C.S. Eng. aged 36.
GAULD—On June 16 in Nottingham George Ogg Gauld M.B. Edin. aged 76.
GRAY—On June 16 in London George Mann Gray M.D. Glasg. F.R.C.S.
WARWICK BROWN—On June 21 at Westgate on Sea Alexander Warwick Brown M.A. M.B. B.Sc. Aberd.
WYNN THOMAS—On June 21 in London Harold Wynn Thomas M.R.C.S. aged 85.

Notes and News

THE LAYMAN AND EPILEPSY

A MEETING is to be held at 1, Wimpole Street, London W.1, on Thursday, July 6, at 5.30 P.M., to inaugurate a society to further the interests of those suffering from epilepsy. Lady Cynthia Coville will be in the chair, and the speakers will include Dr. Russell Brain, F.R.C.P., Dr. Macdonald Critchley, Dr. Letitia Fairfield, and Dr. Denis Williams. The society is being formed under the auspice of, and independently of, the National Association for Mental Health and is receiving support from the British branch of the International League against Epilepsy.

It is hoped that the association will be regarded as a memorial to the late Dr. Tylor Fox, who in his lifetime did much to forward the society's main object "to enable persons suffering from epilepsy to live as normal a life as possible in society, and to educate the public into a rational and sympathetic attitude towards epileptics in all spheres of life, and to enlist the help of people and bodies to bring this about."

CONVALESCENCE FOR DIABETICS

THE ordinary convalescent home does not cater for diabetics: the risk of coma is too dismaying for the matron and the thought of special diets too upsetting for the cook. The Diabetic Association has therefore made arrangements for diabetic patients to be accepted at two homes—men at the British Red Cross Home at Burley-on the Hill, in Rutlandshire, women and children at St. Mary's Home at Birchington on Sea, in Kent.

A diabetic who is being stabilised, or recovering from an intercurrent illness, can profit greatly from a month's convalescence. At the Burley on the Hill home the matron and a trained day sister and trained night staff nurse all have had a good grounding in their specialty. Under their guidance the rest of the nursing staff quickly learn to recognise the signs of hypoglycaemia, usually only encountered in patients who have newly arrived. The house is old and beautiful, set in fine grounds on a wooded hill overlooking a wide stretch of country. It is two miles from Oakham, which—boasting not only the charms of antiquity but also a cinema—is well adapted to the tastes of ambulant patients, and most of them are ambulant, though the home is able to look after two or three bed patients at a time for short periods. To walk to Burley and bus back, and then to walk both ways, is a useful test of progress for able-bodied patients. Entertainments such as dances and cinematograph shows are given in the fine ballroom of the house. The kitchens are simply equipped and staffed by part-time cooks from the village, but they serve good food. The matron studies the diet on which the patient is admitted, and charts his carbohydrate allowance for the 24 hours. Two cooked meals—lunch and dinner—are served daily, with a 20 gramme sweet at each meal, the residue of carbohydrate for each diet is altered by adjusting the weight of bread and potatoes. Ample meat, fish, cheese, eggs and green vegetables are served, and meals are supervised by the matron or sister. A new diabetic is said often to gain half a stone in the first week. Urines are tested before every meal, and in patients who are not stable the blood sugar is also done once a week. The sister pays special attention to the patients' feet and to any perforating ulcer. Diabetic men from any part of England, Wales, or Northern Ireland are accepted here as well as other convalescent patients from the neighbourhood area.

St. Mary's Home at Birchington, is conveniently close to both the sea and the railway station. It can receive 50 patients, who sleep in rooms of 2-5 beds each. Patients with heart conditions, poor vision, or crippling disabilities sleep on the ground floor. Besides three common rooms, there is a recreation hut in the garden, and such diversions are arranged as coach trips to Canterbury, picnics in the neighbouring countryside, and visits to local entertainments. Women and girls over 13 occupy the main building, and children under that age have a separate building, Mansford House, nearer the sea. Adult patients usually stay three weeks, and during that time are taught not only the principles but the details of diabetic feeding, and the technique of injecting insulin.

In Mansford House there is a large playroom on the ground floor, and airy dormitories upstairs with beds for 18 children.

except the toddlers learn to give their own insulin, and are taught about the carbohydrate values of their food and the principles of dieting. The average stay is 4-6 weeks. Non-diabetic children are accepted in this home, but diabetics are first class. A doctor visits weekly, and at other times when necessary. This home was originally sponsored by the Diabetic Association, but is now vested in the Minister of Health and managed by the Isle of Thanet Hospital Management Committee for the South East Metropolitan Regional Hospital Board, but the association is represented on the house committee, and gives generous grants towards the patients' amenities.

HOME NURSING

Home nurses have multiplied as trained private nurses grow scarcer. Mrs. Mary King Hutton, assisted by Dr. S. King Hutton, has written a clear and useful little book¹ for these amateurs, outlining the way the body works and giving advice on the sickroom, the daily care of the patient, nursing of infants, weaning the baby, diets and invalid cookery, and the nursing of various classes of illness and of the very old. All the advice is sound and simply put, and the pictures and diagrams are informative.

CABINET FOR MICROSCOPE SLIDES

Dr. E. Neumark writes, from St. Mary's Hospital Medical School: "The cabinet illustrated here has been devised after a model made several years ago by Prof. W. D. Newcomb. It has four drawers, each accommodating about 800 slides in four lines. The drawers, which can be easily removed, are subdivided by a slanting wooden division, and in one the

back portion is designed to hold rather wider slides. In front of each slide is placed a piece of paper of the same size which may be used for relevant notes, and for classification slightly longer pieces of paper are used. Labels should be attached to the top of the slides and not, as is more usual, at the bottom. The cabinet is of the same size as those for 5 in. by 3 in. record cards, but it is much more strongly constructed and will not break down under the weight of the glass. Two or more cabinets can be stacked by a recessed nesting arrangement of the top. They measure 13 in. by 9 in. and are 15 in. deep. They may be obtained from Messrs. Miller Williams, 6A, Shepperton Road, London, N 1.

North East London Clinical Society

The annual dinner of this society, the first since the war, was held on June 7. Dr. Brian Russell, who was in the chair, proposed a toast to the Society, with the hope that after the many vicissitudes through which it had gone in the past it had now entered a new and long lease of life. Dr. D. B. Handler, in his reply, emphasised that the strength of these societies was dependent upon the support of the general practitioners. Mr. A. Dickson Wright, who was the guest speaker in his address on the History of Quackery, outlined some of the forces which fostered and maintained quackery even in contemporary society. He stressed the need for self-criticism among the profession when confronted by phenomena that still remain unsolved. Mr. Ralph Coyte proposed a vote of thanks to the guest speaker.

¹ Teach Yourself Home Nursing. London: English Universities Press, 1950. Pp. 180. 4s. 6d.

University of London

Prof. Lillian Penson, has been re-elected vice-chancellor, and Mr. J. B. Hunter, F.R.C.S., has been appointed deputy vice-chancellor for 1950-51.

University of Bristol

The following have been successful in recent examinations: **M.B. Ch.B.**—R. J. Ancill, W. A. W. Dutton (with distinction in obstetrics), M. D. Turner (with distinction in public health), P. J. D. Benjafield, H. J. Bland, Margaret H. Buxton (with distinction in child health), E. R. Duchesne, F. V. Eastman, Doreen A. Ellis, C. C. Ewing, Zdenek Fluss, J. C. Gregg, Roy Hill, E. A. Houghton, G. A. K. M. Jahans, Megan D. M. Johnson, H. I. Leigh (with distinction in public health), George Lucas, Jean M. Mensies, G. W. B. Peel, Barbara M. Philpott (with distinction in public health), L. P. Spence, L. A. D. Tover, Joan Walker, C. E. Dickson, Harold Maxwell.

D.P.M. (part II)—M. W. Annear, J. A. Bickford, R. M. Ellison.

D.P.H. (part II)—A. J. Board, E. L. Fawcett.

* With second-class honours. † In group II only.

University of Leeds

Dr. R. Harper has been appointed lecturer in industrial psychology, Dr. W. J. O'Connor senior lecturer in physiology, and Dr. T. K. Marshall lecturer in forensic medicine.

Queen's University, Belfast

At recent examinations the following were successful:

M.D.—C. G. Warnock (gold medal), H. B. McDowell, Mary G. McGeown (with high commendation), W. H. Shepherd, D. W. Wallace (with commendation), N. J. Ainley, S. J. G. Gilmour, S. G. McComb, D. G. Simpson, R. J. Young.

M.B. Ch.B.—B. A. O.—Beatrice A. Russell (second-class honours), W. D. Addis, Vivian R. Boyd, P. G. Buckham, John Burrows, H. L. Courtenay, W. J. Crawford, R. H. Currie, Irene G. Douglas, John Dunlop, Margaret R. Elder, R. M. Ellis, Jean M. Fitzsimons, Patricia Gorman, Elizabeth Hawkins, T. L. Hazelton, W. C. Heron, M. McA. Holmes, Elizabeth L. Houston, Monica Kerrigan, W. J. Love, Martha E. McCormack, J. G. McKenniv, Sheila C. McNally, J. B. McSherry, Maureen E. Magowan, D. C. S. Millar, D. G. Rice, Dorothy E. Robb, John Smith, J. E. L. Sutcliffe.

University of Dublin

Owing to ill health Prof. J. W. Bigger will retire on Sept. 30 from the chair of bacteriology at Trinity College and from the position of dean of the school of physics there. Prof. D. S. Torrens has been appointed assistant dean for the long vacation, and he will succeed Professor Bigger as dean at the beginning of October.

Order of St. John of Jerusalem

The King has sanctioned the following promotions in, and appointments to, this order:

As Knight—J. H. G. Robertson, C.B.E., M.D.
As Commanders—J. C. Ashton, M.B., Sir Horace Evans, K.C.V.O., F.R.C.P., Surgeon Captain Thomas Madill, O.B.E., M.B., R.N.
As Officers—H. S. Taylor-Young, F.R.C.S., Harry Middleton, M.C., M.B., D. A. B. Hopkin, M.B., Colonel F. A. Bearn, C.B.E., D.S.O., M.C., M.D., Brigadier T. W. Davidson, M.B., D. J. Johnson, M.R.C.S., N. M. MacLennan, M.D., B. O. Bradshaw, M.B., Lieut.-Colonel E. H. R. Altounyan, O.B.E., M.C., M.D., F.R.C.S., Isaac Newton, F.R.C.S., Surgeon Captain A. W. McRorie, M.D., K.H.P., R.N., Peter Pringle, M.R.C.S., Lieut.-Colonel E. G. Montgomery, M.B.
As Associate Officers—T. Seshachalam, L.R.C.P., Squadron Leader F. S. Krusin, M.R.C.S.

Welsh National School of Medicine

Dr. Harold Scarborough has been appointed professor of medicine and director of the medical unit. Dr. Scarborough is at present reader in medicine at the University of Birmingham.

Dr. Scarborough graduated M.B. with honours at the University of Edinburgh in 1932. After holding a series of teaching and research appointments in Edinburgh, he spent two years with a Beit fellowship in Prof. G. W. Pickering's department at St. Mary's Hospital, London. Later as a Rockefeller fellow, he worked in Prof. E. M. Landi's department at Harvard till 1947. He joined the staff of the department of medicine at Birmingham. Dr. Scarborough took his F.R.C.P. in 1940 and he became F.R.C.P.E. in 1947. He has published papers on ascorbic acid and vitamin P on the laevulose tolerance test of hepatic function and on stored blood.

I.C.I. Research Establishment

Imperial Chemical (Pharmaceuticals) Ltd. have purchased 350 acres of the Alderley Park Estate, near Manchester, where a research centre will be developed.

Medical Golfing Society

At the summer meeting held at Sunningdale on June 22, The Lancet challenge cup (scratch) was won by Dr. M. J. Healy. The Henry Morris cup (bogey) was also won by Dr. Healy with a return of all square.

International Congress of Microbiology

The fifth International Congress of Microbiology will be held in Rio de Janeiro from Aug 17 to 24 under the presidency of Olympio da Fonseca Filho. Further particulars may be had from the secretary of the congress, Instituto Oswald Cruz, Caixa Postal 926, Rio de Janeiro, Brazil.

Renal Association

At a meeting of this society to be held at the Ciba Foundation 41 Portland Place, London, W 1, on Saturday, July 15, at 11.30 A.M., Dr Homer Smith will give an address on the Development of Modern Renal Physiology. A few tickets will be available to non members and may be had from the hon secretary, Mr John Sophian, 66, Harley Street, W 1.

U.S. Graduates in 1949

A report in the *Journal of the American Medical Association* (June 3, p. 441) shows that during 1949 a total of 5886 doctors received their first licence to practise. In the same period 3600 deaths among doctors were reported. The registration of doctors revealed that 93.7% were graduates of approved medical schools in the U.S.A. and Canada, 4% were graduates of foreign medical faculties.

Biological Hazards of Atomic Energy

A two day conference on this subject is being arranged jointly by the Institute of Biology and the Atomic Scientists' Association and with the support of the British Association. It will be held at the Royal Institution, Albemarle Street, London, W 1, on Friday and Saturday, October 20 and 21. The meeting will comprise four sessions as follows: I. biological and medical effects of nuclear radiations, II. tolerance levels and measures of protection, III. biological implications, IV. atomic energy and the future. The chairman of the organising committee is Prof Alex Haddow, Chester Beatty Research Institute, Royal Cancer Hospital, Fulham Road, London, S W 3.

Society of Chiropractors

In opening the fourth annual convention of this society Sir Cecil Wakeley, F.R.C.S., regretted that in this country we were not more conscious of foot health, for foot health makes for a contented populace, and he believed that chiropractors can relieve pain in 90% of painful feet. Co-operation between the medical profession and the chiropractors was important. He knew that this co-operation was working well between the consultant and specialist and the chiropractor, but he was not convinced that it was working as it should between the general practitioner and the chiropractor. This was a pity for in a comprehensive health service co-operation was essential between the medical profession as a whole and the medical auxiliaries.

To round off their convention on June 23 the society held their annual dinner at the Park Lane Hotel, London, with their president, Mr J. H. Hanby, F.R.C.S., in the chair. In proposing the toast of The Society, Lord Webb-Johnson recalled the support which the Royal College of Surgeons had been happy to give to the profession in its early days. The position of auxiliaries was also stronger if they were banded together, and he was glad that the chiropractors had started from the right place with a firm code of ethics and professional standards and with one guiding authority to represent the whole profession. He hoped that the scope of their work would grow like a callus. Perhaps their greatest service to the community would be their preventive work among the children which he was sure would soon discredit the old saying that in the morning you sow your seed but in the evening you cut your corn. In his reply, Mr Hanby was happy to agree that the society was going from strength to strength. It was emerging as a national body, and on the new Whitley Council it was representing the profession of chiropractic. As a society they had made a good start under the guidance of such men as Mr E. G. V. Runtz, the doyen of the profession, and they were also grateful for the co-operation and guidance which the medical profession had always offered them. In proposing The Guests Miss C. F. Norrie, F.R.C.S., a vice president, was able to welcome representatives of law and medicine, other medical auxiliaries, nurses, negotiators, and lay members of branches and committees of the National Health Service. As last man in, Sir Horace Evans returned graceful and lighthearted thanks which delighted both his fellow guests and his hosts.

International Society of Medical Hydrology

A meeting of this society will be held in Italy in Florence from Oct 3 to 7. The programme includes discussions on Sweat and on Gout. Further information may be had from Dr Donald Wilson, Cranbourne, Southdown Road, Bex Regis, Sussex.

Royal Statistical Society

At the 118th annual general meeting of this society the following elections were announced: president, Prof Brad Hill, D.Sc., hon secretaries, Mr R. F. George, Mr R. H. Stone, Mr Philip Lyle, hon treasurer, Mr R. F. Fox. Mr H. Campion, of the Central Statistical Office, was awarded the society's Guy medal in silver.

Retiral of Dr Graves

Dr T. C. Graves, medical superintendent of Rubens Hospital for the past thirty years, and president of the British Medical Psychological Association from 1940 to 1944, retired this week. Presentations made to him at a farewell luncheon on June 15 included an illuminated album, in which was noted his "distinguished service to Medicine in the control of mental and physical disease."

International Conference on the Venous System

From Sept 15 to 17, after the International Congress of Cardiology, which is taking place in Paris from Sept 3 to 6, the medical societies of Marseilles and Aix-en-Provence, under the auspices of the Marseilles Medical Faculty, are holding at Aix-en-Provence an international conference on the venous system. Prof René Leriche will preside, and Professor Roscam (Liège) will read a paper on the Biochemistry and Medical Treatment of Venous Thrombosis, and Professor Fontaine (Strasbourg) on the Early Surgical Treatment of Venous Thrombosis. Further information may be had from Dr Beurrier, joint general secretary, 4, Cours Mirabeau, Aix-en-Provence.

CORRIGENDA *Rheology of Human Cervical Secretions*—In the preliminary communication last week (p. 1164) by Mr A. F. Clift, Mr F. A. Glover, and Dr G. W. Scott Blair, the legend of the figure should have opened with the words "Average log (slope) of cervical secretions."

Claims to Sickness Benefit—These claims, which were enumerated in last week's issue (p. 1178), are made under the National Insurance Act, and the figures are published by the Ministry of National Insurance.

INVESTIGATION OF THYROID FUNCTION AND DISEASE WITH RADIOACTIVE IODINE *

E E POCHIN

M.D. Camb., F.R.C.P.

DIRECTOR, DEPARTMENT OF CLINICAL RESEARCH, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

IT IS NOW ten years since a radioactive form of iodine was first used in the investigation of human thyroid disease, and the early work of Hamilton and Soley (1940) and of Hertz (1941) has been extended to a number of clinical problems. The physiological study of the human thyroid by this method has, however, lagged somewhat behind the clinical applications, so that certain measures of thyroid function in disease tend to be empirical and incompletely understood. The normal behaviour of the gland has therefore been examined by radioiodine and related to certain abnormalities in disease.

It is characteristic of the early phases of any new method of investigation that the method itself appears to acquire a merit quite apart from its value in solving important problems. This is to some extent healthy if its full scope and applications are to be rapidly explored. It may readily result, however, in a search for isolated and random problems to which the method is applicable, rather than in the necessary integration of the new with the older techniques of study for the closer analysis of questions of outstanding importance. In describing certain applications of radioiodine to the study of the thyroid, therefore, I do not wish merely to enumerate problems to which this valuable technique may be applied, but to suggest ways in which it may ultimately be woven into the full pattern of thyroid investigation.

The metabolism of iodine is clearly of the greatest importance in thyroid function and in much of thyroid disease, and its detailed study by chemical methods has been outstandingly valuable and successful. The purely chemical method, however, has reached certain limitations, arising from the small quantity of inorganic iodide present in the plasma and the delicacy required in its determination, from the impossibility of estimating rates of synthesis without giving physiologically excessive quantities of iodine, and, above all, from the difficulty of any adequate study in living men. The iodine content of the human thyroid cannot be examined or followed except at biopsy, operation, or autopsy, and the circulation of iodine through the body can barely be estimated even by the most indirect methods.

In 1938 radioactive forms of iodine became available which were chemically indistinguishable from normal iodine and therefore metabolised identically, yet could be recognised by their radioactivity and thereby estimated quantitatively and followed in their passage through the living body (Hamilton 1938). Several limitations of the purely chemical method were removed at once: for example, radioiodine can be detected in very small quantities in body fluids by measurement of its beta-radiation, while its gamma radiation, which penetrates body tissues freely, allows the concentration in different parts of the body to be followed during life. Accurate investigations can be made on man after a dose of radioactive iodine which is too small either to produce any significant effects upon the body by its radiation, or to

disturb the course of metabolism by the amount of iodine that it contains—which is normally less than a thousandth part of a microgramme. Yet, since the administered iodine is recognisable by its radioactivity, we may detect the time of its arrival in different parts of the body, or of its conversion into different chemical forms. The speed of its metabolic cycle through the body, and the dynamics of its chemical equilibria, may thus be determined. Hence the line of thyroid investigation, particularly in man, has moved rapidly forward, owing largely to several groups of investigators, including Hamilton, Keating, Astwood, Rawson, and Quimby, whose extensive and valuable work has been well summarised (Astwood and Stanley 1947, Keating and Albert 1949, Kelsey et al 1949, Raben and Astwood 1949, Rawson 1949, Rawson and McArthur 1947, Skanse 1949) and will not be reviewed here.

In the following discussion I will deal with the normal uptake of radioiodine by the thyroid gland and abnormalities of uptake in thyroid disease, the methods for measuring the rate of uptake, and their clinical application, the later phases of the body iodine-cycle, in the thyroid and after discharge from the gland as thyroxine, and measurements of the localisation of radioiodine, particularly in cases of carcinoma of the thyroid.

Methods of Measurement

The thyroid uptake of radioiodine and its subsequent circulation through the body may be followed in some detail by measurements of a few simple types, particularly on the plasma and the urine and opposite the thyroid gland. If a suitable Geiger counter is placed near any radioactive source, impulses are emitted from it at a rate proportional to the radioactivity of the source. So, for example, if plasma is taken from a subject who has received radioiodine, and is poured into a glass chamber surrounding a counter tube, the counting rate which results will be directly proportional to the radioiodine concentration of the plasma. This concentration may be expressed as a percentage of the dose given per litre of plasma, by comparing the counting rate with that of a standard solution from which the dose was prepared. The disappearance of an intravenous dose of radioiodine from the plasma may be followed with considerable accuracy by this means.

Similarly, if urine samples are tested in this way, and if their volume is known, the total percentage of the dose which has been excreted by the kidneys at any time may be computed. The same method has been used in measuring the activity of saliva and other fluids which will be discussed, and is clearly also applicable to separate examinations of different chemical fractions of these fluids. We have distinguished between radioiodine in the forms of iodide and combined in thyroxine, by the butanol fractionation method of Taurog and Chalkoff (1947), and we have used precipitation methods so that the protein bound radioiodine of plasma could be separately estimated. In each case the radioiodine concentration or the radiothyroxine concentration can be expressed as a percentage of the dose given, by comparison with a standard solution.

A similar principle applies to the radioactivity of the thyroid gland itself, and the counting-rate at a given distance from the gland will be proportional to the thyroid radioiodine content. Variations in this content may therefore be followed if a counter is placed in front of the neck opposite the gland (fig. 1), and is suitably shielded with lead from the radiations of radioiodine elsewhere in the body. Provided the neck position relative to the counter is kept constant, and the radioiodine content of the neck tissues other than the thyroid

* The Oliver Sharpey lectures delivered at the Royal College of Physicians of London on March 14 and 16. Based on work undertaken for the Medical Research Council, in conjunction with B. D. CORBETT, B.A., the late E. A. G. GOLDIE, M.B., A. J. HONOUR, and N. B. MYANT, B.M.

Fig 1—Lead shielded gamma counter in front of neck

is relatively small, as is usually the case, then the counting rate is proportional to the radio iodine content of the thyroid

This thyroid content may also be expressed as a fraction of the dose given, by observing the counting rate with the counter at a known distance from the thyroid. This rate is then compared with the counting-rate observed when the counter was at the same distance from the original dose of radio iodine, measured before its administration. To make this comparison, however, it is necessary to know, firstly, how the neck tissues surrounding the thyroid modify the counting rate, and secondly, the exact position of the radio iodine in the neck.

The first problem was examined by separate experiments in which a radio iodide solution was injected into a short length of the lumen of a Ryle's tube (Myant et al 1949b).

This tube was first hung in air at a known distance from the counter, and the counting rate recorded. It was then

swallowed so that the dose lay in the oesophagus at the level of the thyroid gland, its exact position being determined by lateral X ray examination and the counting rate was again recorded with the counter at the same distance from the tube. It was found that the neck tissues surrounding the radio iodine caused an increase in the counting rate by about 26% in the twelve subjects examined, a forward scattering

Fig 2—Percentage of intravenous dose of radioiodine in thyroid, urine and tissues; average of 12 normal subjects

of secondary radiations into the counter outweighing the small absorption of primary radiations by these tissues. A suitable allowance for this effect can thus be made when estimating the thyroid content in other subjects.

The same experiments were used to examine the way in which the counting rate falls as the distance between counter and source is increased. It was found that, with radio iodine in the neck, as with any small radio

active source in air, the counting rate varies with the inverse square of the distance between counter and source. Consequently, the reciprocal of the square-root of the counting rate increases linearly with distance between counter and neck, as this is varied, and the position of the source in the neck can be accurately determined by this means to within a few millimetres (Myant et al 1949b).

It is therefore possible, as with the urine and the plasma, to express the amount of radio iodine in the thyroid gland as a proportion of the dose given, with an error which is probably in the region of 5% of the value estimated. With this information, which is obtained without disturbance even to thyrotoxic subjects, and with knowledge of plasma and urine concentration, it is possible to examine the course of radio iodine circulation through the body in a quantitative way, after the oral or intravenous administration of a solution of the radioactive element in the form of iodide.

Distribution of Radio-iodide Through Body Tissues

Since radio iodide is taken up by the thyroid and the kidneys at a rate which depends upon its concentration in the plasma at the time, it is necessary to examine

Fig 3—Comparison of non thyroid tissue content with plasma concentration in estimation of iodide space. Subjects as fig 2.

the initial extent of radio iodide diffusion through the body, before the course of its thyroid concentration can be examined in detail. This body distribution may be estimated from the measurements already discussed, which serve to determine both the radio iodide space and the speed with which it is filled. In fig 2, the average thyroid and urinary content of radio iodine (expressed as percentages of the dose) is given for the first 6 hours after intravenous administration in a group of twelve normal young subjects. Since faecal and other excretions are small, the amount remaining in blood and non thyroid tissues is obtained by subtracting the thyroid and urinary contents from the total dose. The results (fig 2) show that half the administered dose had been removed from the tissues by thyroid or kidneys within 4 hours. If this total extrathyroid tissue content is compared with the plasma concentration (fig 3) the radio iodide space may be calculated. For example, since the tissues contain 60% of the dose when the plasma contains 3% of the dose per litre, the space would have to have a volume of 20 litres if it contained radio iodide at the concentration present in plasma. The radio iodide space, so estimated, increases rapidly for the first two hours after the dose, then approaching a limiting value of about 25 litres. Hospital patients without thyroid disease have also been found to have normal radio iodide spaces (Myant et al 1950), rising to a final value of about 25 litres, or 40% of the body-weight

the radio iodide space in Graves's disease has been greater than normal at one hour, as Keating and Albert (1949) have also found

As with similar conventional diffusion spaces for sodium or thiocyanate, it cannot be inferred that an anatomical volume of this size is actually filled with fluid at a radio iodine concentration equal to that in plasma. It has been shown, for example, that gastric

Fig 4—Penetration of radio-iodide into thigh tissues in normal subjects after intravenous dose ranges ± 2 S.E.

juice and saliva contain iodide at concentrations many times that of plasma (Schiff et al 1947). We found that in the group of twelve normal subjects the average salivary concentration of radio iodide fell from over 200% to about 50% of the dose per litre, while the plasma concentration fell from 7 to $1\frac{1}{2}$ % per litre, the saliva collected in the mouth containing radio iodide at about thirty times the concentration prevailing in the plasma half an hour previously (Myant et al 1950). It has also been confirmed that gastric juice contains radio iodide in the same greatly raised concentrations of about thirty times that in plasma—which is about the concentration ratio observed in urine compared with plasma. These high concentrations of the iodide ion are of some physiological interest and might possibly prove to have radiotherapeutic value. Conversely, the normal cerebrospinal fluid contains iodide in concentrations lower than in plasma. In ascitic fluid, measured during its aspiration, and in cardiac oedema fluid, obtained during its removal by Southey's tubes, radio iodide approaches the plasma concentration with a delay of an hour or two, which is similar to that for the body tissues as a whole, as indicated by the progressive rise of the iodide space observed during the first few hours after the dose.

An alternative and more direct estimate of the entry of iodide into the tissues may be obtained from a sample area such as the thigh. If the radioactivity of the thigh as a whole is followed by a gamma radiation counter placed near it, and if the counting rate observed is compared with that of the plasma, we can obtain a measure of the completeness with which radio iodide at plasma concentrations has diffused throughout the thigh, and the same rather slow equilibration is found to occur (fig 4). The diffusion in patients with Graves's disease is again either more complete or perhaps merely more rapid than normal (Myant et al 1950).

First Phase of the Iodine Cycle Thyroid Uptake of Iodide

As radio iodide diffuses from the blood stream into the tissues, or is concentrated in the alimentary secretions, its plasma concentration falls correspondingly. Meanwhile, however, both the thyroid and the kidneys are removing iodide from the plasma that circulates through them. We may picture radio iodine, introduced in the form of iodide into the circulation (fig 5) either intravenously or by absorption from the alimentary tract, diffusing into the tissues, and being progressively removed either by the thyroid or the kidneys. When the actual rates of renal and thyroid removal are examined, these

rates are found to run proportional to the concentration of radio iodide in the plasma at the time.

RENAL CLEARANCE

When the renal excretion rate is plotted against plasma radio iodine concentration, the two are found to be directly proportional to each other. In a group of subjects so examined (Myant et al 1949a), the kidneys excreted 8% of the dose per hour while the plasma contained 4% per litre, and 6% per hour while the plasma contained 3% per litre, the hourly excretion always amounting in fact to the quantity of radio iodide contained in 2 litres of plasma. In other words, as with the familiar renal clearances for such substances as urea or inulin, the kidney clears a constant volume of plasma each hour of the radio iodide it contains, the normal kidney clearing about 2 litres of plasma each hour. This implies that whatever iodide is present in this volume is also excreted, since radio iodide is not distinguishable chemically from normal iodide. We have, therefore, a method of estimating the renal clearance of iodide by comparing the rate of urinary radio-iodide excretion with the simultaneous level of its plasma concentration. This renal clearance has about the same value in normal subjects and in patients with Graves's disease. In different individuals, however, its value varies widely round a mean of 32 ml. of plasma cleared per minute with a standard deviation of 12 ml per minute. Since red blood cells are found to take up iodide rapidly to a concentration about two thirds that in the plasma, the plasma clearance of 32 ml per minute is equivalent to the removal of iodide from 37 ml of blood per minute. It is of interest that, since the renal blood flow is estimated at about 1200 ml per minute (Goldring et al 1940), the kidney removes the iodide passing through it with an efficiency of about 3% at physiological plasma iodide levels.

THYROID CLEARANCE

A thyroid clearance rate for iodide can be estimated in a somewhat similar manner. Thus if the counting-rate opposite the neck is plotted, the curve obtained indicates the amount of radio iodine in the thyroid, and the slope of the curve measures the rate at which radio iodine is being accumulated by the gland at any time. This rate of uptake is also found to run parallel to the plasma radio iodine concentration in the early hours after the dose and before radio-iodine liberation from the gland, and thyroxine accumulation in the plasma, disturb the proportionality. During these hours, therefore, a thyroid clearance can be calculated. For example, suppose that the rate of rise of the neck-

Fig 5—Initial circulation of radio-iodide

count indicates a thyroid uptake rate of 8% of the dose per hour, and that the plasma at the same time contains 4% of the dose per litre. It can then be said that the thyroid is clearing $1\frac{1}{2}$ litres of plasma of its radio iodide per hour.

Again, since radio iodide is chemically indistinguishable from normal iodide, this clearance rate gives a valid method of sampling thyroid activity at a given level of plasma iodide. Moreover, evidence is accumulating that this rate varies little with moderate changes of plasma iodide level within the normal range. The thyroid clearance rate for radio iodide therefore appears to measure directly that avidity of thyroid tissue for circulating iodide which is characteristically affected in Graves's disease. In thyrotoxic subjects also, the uptake rate is proportional to the plasma concentration, but a much greater volume of plasma is cleared each minute and this is commonly observed even in clinically mild cases of Graves's disease. The actual weight of iodide taken up by the thyroid will depend not only on the clearance rate, but also on the plasma iodide concentration (Stanley 1949). The overactive gland, however, removes iodide faster than the normal one from plasma of equal iodide content, and the thyroid clearance rate is the direct measure of this greater avidity.

The normal thyroid clears on average 25 ml of plasma per minute. As with the renal clearance, the value does not imply that this quantity of plasma is cleared with complete efficiency. To investigate the actual efficiency with which the thyroid removes iodide, we have measured, during operations for simple thyroid adenoma, the difference in radio iodine concentration in blood from a thyroid vein and from an arm vein.

After a radio iodine dose an hour previously, blood is taken from a vein draining the more normal of the thyroid lobes. It is difficult to avoid either stasis in the vein if it is occluded, or withdrawal of blood from proximal veins draining other tissues if occlusion is not used, and very variable results have been obtained in the six cases examined. The mean value, however, corresponds to a removal by such thyroid tissue of about 20% of the radio iodide passing through the gland. Since the normal clearance is equivalent to 30 ml of whole blood cleared per minute, this figure, if valid for normal tissue, would indicate a thyroid blood flow of the order of 150 ml per minute, or about 6 volumes of blood per volume of tissue per minute.

This is a very rough estimate, which could be improved by taking samples from normal glands during operations in adjacent fields. For clinical purposes, however, it is the actual uptake of radio iodide, rather than the total offered by the circulation, which is of major interest, and it is this value which is estimated by the thyroid clearance rate. We have found the clearance-rate to range from 7 to 42 ml per minute in different normal subjects or patients without thyroid disease. In a given subject, the value appears to be relatively constant in successive hours and, for the few cases examined repeatedly, on successive occasions. In a series of twelve healthy young adults, the average value was 25 ml per minute and the standard deviation 8 ml per minute. On the other hand, in 21 patients diagnosed as having Graves's disease, values have ranged from 85 ml to over 500 ml per minute, with an average value of 240 ml. The thyroid clearance is evidently a highly sensitive measure of thyroid over activity compared, for example, with the basal metabolic rate, of which the value is rarely even doubled. As a direct and quantitative measure of the thyroid gland's avidity for iodine, it is likely to be a valuable tool in the investigation of Graves's disease, and of the factors—whether in the pituitary or in

the patient's environment—which may increase thyroid activity. The main interest of this measurement will probably lie in its application to research on the physiology of human thyroid function, and on the mechanism of pathological hyperthyroidism and hypothyroidism.

As a diagnostic criterion also, however, it appears to have substantial value, particularly in cases suspected of early or slight thyrotoxicity. It is difficult on only two years' experience with the method to define a clinical reliability, especially in the absence of any conclusive and objective measure of thyrotoxicity. In our opinion it is more reliable than the basal metabolic rate, and is of clear value in distinguishing the mildly thyrotoxic patient from the subject with anxiety symptoms but without metabolic change, in whom the clearance is found to be normal.

The thyroid clearance would be completely reliable as a test of Graves's disease, only if its value were always raised beyond the normal range even in the mildest cases and if no other disease caused a similar rise. In view of the differences in clearance rate even between normal subjects, a complete separation could not be expected, but the overlap between the groups may be small enough to give a clinically valuable test. We have not examined large series of patients to investigate these points fully, but in all recent tests in which reliable methods of calibration have been used, we have not obtained evidence of overlap between the groups. We have not yet observed clearances of over 45 ml per minute in normal subjects, or of over 65 ml in patients with simple goitre. We have not seen values below 80 ml in probable Graves's disease, and most values exceed 100 ml even in clinically mild cases, or 150 ml in the fully developed disease. The highest clearances, however, are not found in patients with the highest basal metabolic rates, nor in those cases which appear to be most severe on clinical grounds, and the clearance rate may correlate with the vascularity of the gland rather than directly with its toxicity. These values refer to untreated cases, and the clearance is considerably reduced during therapy either with thiouracil derivatives or with Lugol's iodine at therapeutic dosage. In so far as a rapid iodide uptake implies a rapid thyroxine output, the clearance would be expected to give some measure of the degree of thyrotoxicosis. If, however, the conversion of iodide to thyroxine is chemically blocked by thiouracil, it cannot be expected that the iodide clearance would continue to measure the level of metabolism. The clearance, and tests depending on it, cannot therefore be relied on to follow a response to medical treatment.

In myxœdema, the uptake of iodide by the thyroid is usually detectable, although it is too small and too slow for accurate determination of the clearance. Rough values may be estimated, however, and, for cases in

Fig. 6.—Relation of urinary output of radio-iodide to thyroid clearance rate. Curves a predicted mean and extreme values as in text. Black discs Graves's disease; open circles no thyroid disease.

Fig 7—Relation of "neck thigh ratio" to thyroid clearance-rate

which the clinical diagnosis is clear, range from 1 ml. to 4 ml. per minute in place of the normal clearance of 25 ml. per minute. It is to be expected that the diagnosis of minor degrees of hypothyroidism would be greatly simplified by determination of the thyroid clearance

TESTS OF IODIDE UPTAKE

As a practical measure, determination of the thyroid clearance rate is regarded by the thyrotoxic patient as no more upsetting than determination of the basal metabolic rate, and indeed the former is often preferred. The thyroid clearance test has, moreover, the advantage that, with radio iodide given intravenously, it can be done at any time of day on an outpatient and can be completed within an hour. It is undoubtedly rather more complex, however, than determination of the metabolic rate, in respect of equipment, measurements, and calculation, and simpler, if less direct, indices of thyroid uptake have been used or may be suggested. Many of these are based on urinary excretion of radio-iodide since, if the thyroid uptake of iodide is increased, the kidney secures a correspondingly smaller share of the test dose. The percentage of the radio iodide excreted within 24 hours, or some other given period, will therefore depend partly on the thyroid clearance. Many reports have indicated a low excretion in Graves's disease, less than 25% of the dose usually being passed in 24 hours, as compared with over 40% in most normal subjects. Unfortunately, as has often been emphasised, an output of about 30% may be obtained from some normal subjects as well as from subjects with clear or suspected Graves's disease. While this test commonly gives valuable evidence, therefore, an ambiguous answer may be obtained from those cases of mild Graves's disease in which diagnostic information is most desirable. Such overlap between the results is to be expected since the thyroid uptake is inferred from the renal output, and since the renal clearance rate is itself a highly variable factor in different subjects. When the 24 hour urinary excretion of radio iodide is plotted against the thyroid clearance in normal and thyrotoxic subjects (fig 6), the urinary excretion is seen to be inversely proportional to the thyroid clearance, but individual points scatter rather widely from a line. The central line is that calculated by assuming average values for renal clearance and for the extrathyroid tissue content of radio iodine at 24 hours. The boundary lines show the error that would be predicted from the observed variability of these values in different individuals, at the two standard deviation level. It will be seen that the points group round the curve within approximately the predicted zone, showing that known causes of variability account for the observed

uncertainty of the test based on 24-hour urinary output. Moreover, it is clear that a high normal clearance of 40 ml. per minute could, for these reasons alone, be associated with a 24-hour output lower than that which could accompany a low thyrotoxic clearance of 100 ml. per minute, showing that overlap would be expected in the zone in which it is observed. It appears that, whether or not normal thyroid clearances and those in Graves's disease prove to overlap in value, inferences of thyroid uptake that are based on renal excretion must be subject to a greater degree of overlap, owing largely to the variability of the renal clearance for iodide.

The same criticism applies, although with somewhat less force, to tests based on the urinary excretion during an optimal period—for example from 8 to 12 hours after the dose—when the normal output may exceed that in Graves's disease most consistently. It will be remembered that the urinary output of radio iodide is determined by the plasma concentration and the renal clearance rate. The urinary excretion rate must therefore always be less reliable than the corresponding plasma radio iodide concentration, which gives precisely the same information but without involving the variability of the renal clearance.

Because of this occasional difficulty with the otherwise simple and valuable urinary test, Keating et al (1947) proposed a mathematical analysis of the roughly exponential course of urinary output. They suggested that the fall in plasma concentration is due to thyroid and renal removal of iodide. If, therefore, the renal contribution to the total were assessed, the thyroid removal of iodide could be estimated by difference. This method, has, however, a limitation which its authors have emphasised (Keating and Albert 1949). As we have seen, removal of iodide from the plasma into the extrathyroid tissues is an important additional cause for the fall in plasma concentration for several hours after the dose, and in some cases, by the time this factor becomes unimportant, the fitting of an exponential coefficient to the remaining urinary excretion may involve substantial uncertainty.

For these reasons it is useful to consider other simple measures of thyroid uptake that would correlate closely with the thyroid clearance rate. The total radio-iodine uptake of the thyroid is little better than the 24-hour urinary output, from which it clearly differs only by eliminating a small extrathyroid-tissue content, since these three contents, with a negligible faecal excretion figure, must account for the total dose. We have found overlap between normal and thyrotoxic patients at thyroid uptake levels of about 70% of the dose.

The theoretical advantage of basing such tests on plasma rather than urine samples has already been mentioned. The overactive thyroid in Graves's disease lowers the plasma radio iodine content more rapidly than in normal subjects. The normal plasma concentration still exceeds 2% per litre at 2 hours after the dose, but in thyrotoxic subjects lower values have consistently been observed, except in one subject, in whom absorption of an oral dose was delayed (Myant et al. 1950). After 4 hours the normal values are also falling to low levels, while some Graves's disease patients with rapid thyroxine synthesis, have rising curves for total plasma radioactivity, due now to radio-thyroxine. If a simple test were required which could be based on liquid counting methods alone, the plasma

concentration at, say, 2 hours after an intravenous dose would repay investigation

An even simpler test of comparable value may be obtained by comparing the count opposite the neck with that opposite the thigh. In Graves's disease, the thyroid rapidly takes up radio iodine from that circulating through the rest of the body. The thyroid-count therefore becomes abnormally high and the thigh count abnormally low, so that the ratio between the two is greatly increased. When the value of this ratio—for example, 1 hour after the dose—is compared with the value of the thyroid clearance in different subjects (fig. 7) it is seen that this "neck to thigh ratio," which can be determined in a few minutes, correlates closely with the thyroid clearance, which requires an hour for its estimation. The test is convenient for clinical use in other ways: it requires only a small radio iodine dose, 8 microcuries (μC) being enough for an estimation, whereas we use 30 μC for a thyroid clearance, and the size of this dose need not be accurately standardised, since the result of the test depends on a ratio between counting rates. This test does not involve blood samples or the collection of urine specimens, and the result may be known within an hour of first seeing the patient. At the same time it is more liable than the thyroid clearance rate to be disturbed by extraneous factors, such as thigh size, thyroid position relative to the counter, and variability in the delay of radio iodide absorption from the stomach if the dose is given orally, and the dose should therefore be given to a fasting patient or by intravenous injection. Under these circumstances the test gives, within a few minutes, information which appears to be of considerable diagnostic value in cases suspected of thyroid overactivity.

It appears, therefore, that several simple if indirect measures of the thyroid's avidity for iodine may be derived from measurements of urinary, plasma, or external body counting rates. Where such tests are used in the diagnosis of hyperthyroidism and give an equivocal result, the thyroid clearance rate is more likely to be conclusive, since it measures this rate of iodide uptake directly. And in so far as the rate of iodide uptake corresponds to the rate of output and utilisation of thyroxine, the thyroid clearance rate should measure the state of the body thyroxine metabolism. More direct information on the thyroxine phase of the iodine cycle can, however, be obtained with radio iodine and by considering the circulation of radio iodine through the body, and its acceleration in Graves's disease.

(To be concluded)

a remarkable change has come over agriculture in all the more advanced countries of the world during the last 100 years. In former ages (and still today in the Balkans and in India) every field of wheat contained thousands of quite different plants, every orchard contained many different trees. Today there are fewer different kinds of wheat or apples in the whole of England than there were formerly in one field or one orchard. Today each of these kinds lasts long and spreads far.

This is a wonderful world for the seedsman and the trader, and at first sight, for the cultivator as well. They all like a standard article. But it is a still more wonderful world for the diseases. The disease organism, whether it is a scale insect, a rust fungus, or a virus, no longer needs by its own adaptations to fit a key to every one of a million different locks. When it fits one it fits them all. How different is the case as I described it in nature where the plant or animal is continually selected to resist to disease continually adapts itself, and exists in unlimited variety reproduced anew every year. Now the dice are loaded against the product of plant breeding. Perfection multiplied, standardized and invariable, is bound hand and foot helpless to defend itself against the variable and resourceful attacker.—C. D. DARLINGTON

SYNERGISM AND ANTAGONISM AS DISPLAYED BY CERTAIN ANTIBACTERIAL SUBSTANCES

JOSEPH W. BIGGER

M.D., Sc.D. Dublin, F.R.C.P., F.R.C.P.I.

PROFESSOR OF BACTERIOLOGY, TRINITY COLLEGE, DUBLIN

It has already been shown (Bigger 1944, 1946, 1947) that two antibacterial substances may display either synergism with or antagonism to one another when acting on bacteria in a culture medium.

This paper records the results of an investigation undertaken to determine the interaction of several antibacterial substances when tested in pairs against *Bacterium coli* in a synthetic medium. Such a medium was used in preference to broth because one of the substances to be investigated was sulphathiazole, and broth, even after treatment by Harper and Cawston's (1945) method, contains sulphonamide antagonising substances which are not present in the synthetic medium used. The medium, which was a modification of one described by Gale (1947) had the following composition:

Glucose	80 g
Ammonium phosphate ($(\text{NH}_4)_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$)	5.0 g
Sodium chloride	1.0 g
Ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$)	0.3 g
Magnesium sulphate ($\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$)	0.7 g
Potassium dihydrogen phosphate	0.5 g
Dipotassium hydrogen phosphate	5.0 g
Water to	1000 ml

pH adjusted to 7.5

As a result of precipitation of phosphates occurring during heating, the concentrations of iron, magnesium, and phosphate in the medium used were considerably lower than stated in the formula.

The strain of *Bact. coli* used in the investigation grew rapidly and well in this medium, but, for reasons which will be dealt with in another paper, 'Lab. Lemco' was added to the medium to give a final concentration of 1 in 20,000.

The substance or substances under investigation were dissolved in the medium, the pH of which, after the addition, was in all cases adjusted to 7.5. Serial dilutions were made in 5 ml volumes of the medium contained in small bottles covered with loosely fitting aluminium cap.

Bottles were inoculated by adding to each one drop from a Dreyer pipette of a suitable dilution in buffered saline of a 24 hour culture of the organism grown in the medium. The bottles were incubated at 37° and were examined daily for 3 days. The naked eye appearance of the medium was recorded as:

C = Clear

T = Slight to moderate turbidity

TT = Marked to full turbidity

One loopful (5 mm loop) from each culture which had remained clear was spread over the surface of an agar slope which was incubated. The colonies which developed were counted. It was possible to count up to several hundred colonies on a slope. When the number was too great to permit accurate counting, the growth was recorded as:

+ = Colonies uncountable
++ = Confluent growth

No great accuracy is claimed for this method of estimating the number of living bacteria in a culture, but it has the advantage over other methods of economy of time, material, and apparatus. It is of considerable value to be able to estimate, even if without a high degree of accuracy, the number of living bacteria in a culture which may contain up to several million living bacteria per millilitre without detectable loss of clarity.

DEFINITIONS

There are not, so far as I am aware, any universally accepted definitions of the terms synergism and antagonism in the sense in which they are used in this paper, and for going further, I must define them.

When two antibacterial substances acting together, each in a specified concentration for a specified time and under specified conditions on a certain number of bacteria reduce the number to a lower level than does each of the substances acting alone in the concentration in which it was present in the mixture and under the same conditions, the two are said to act synergistically. Synergism should be distinguished from the potentiation on which a substance which is not itself antibacterial can exercise on an antibacterial one.

When two antibacterial substances acting together for a specified time under specified conditions on a certain number of bacteria, fail to reduce the number to a lower level than does one of the substances acting alone in the concentration in which it was present in the mixture and under the same conditions, the second substance is said to behave antagonistically to the first.

RESULTS

The investigation was confined to a study of six substances—sulphathiazole, penicillin, streptomycin,

TABLE I

Penicillin (units per ml.)

'Chloromycetin' (chloramphenicol) boric acid, and the sodium salt of *p* aminosalicylic acid—acting in pairs in Lemco synthetic medium on *Bact. coli*.

It is unnecessary to state in detail the results given by the fifteen combinations; a few examples will suffice. The method of presentation is illustrated in table I, which shows the synergistic action of penicillin and sulphathiazole. The bottles of Lemco synthetic medium, containing penicillin or sulphathiazole, or both, in the concentrations shown, were so inoculated that each gave 24 colonies per loop. After incubation for 22 hours, one loopful of each was spread over an agar slope. The number of colonies which developed on incubation are recorded in the table.

The bottom line gives the number of bacteria which survived the action of penicillin alone in the concentrations shown in the top line. The right-hand column

TABLE II

Streptomycin (mg per 100 ml.)

Sulphathiazole (mg per 100 ml.)	Streptomycin (mg per 100 ml.)

Incubation—20 hours

gives the number of bacteria which survived the action of sulphathiazole alone in the concentrations shown in the left-hand column. The rest of the table shows the number of bacteria which survived the combined action of penicillin and sulphathiazole. Penicillin alone, in a concentration of 16 units per ml., permitted the bacteria to grow sufficiently to give rise to heavy turbidity. Sulphathiazole alone, in a concentration of 1/4 mg per 100 ml., permitted 95 bacteria per loop to survive. The combination of the two substances in the same concentrations yielded a count of 0 per loop.

Table II shows another example of synergism—between streptomycin and sulphathiazole. The combination of 1/8 mg streptomycin per 100 ml and 1/8 mg sulphathiazole per 100 ml. yielded 1 colony, as compared with uncountable colonies with the same concentration of sulphathiazole alone and heavy turbidity with the same concentration of streptomycin alone. Synergism in this case is marked, for the count of 1 is less than was yielded by four times the concentrations of streptomycin or of sulphathiazole alone.

In some cases, one of the two substances was found to act synergistically with the other at one range of concentrations and antagonistically to it at another. Table III shows this double action of chloromycetin in relation to sulphathiazole. Chloromycetin in a concentration of 1/4 mg per 100 ml. acted synergistically with sulphathiazole in concentrations of 1/16 and 1/64 mg

TABLE IV

Boric acid (%)

0	0	1	4	—	—

Initial count—25
Incubation—46 hours

per 100 ml., but antagonistically to it in concentrations 16, 4, and 1 mg per 100 ml. It should be noted that these were the results at the end of 20 hours' incubation. When incubation was prolonged to 72 hours, the antagonism gave place to synergism. In such cases as this, the antagonism is regarded as transient.

Antagonism was by no means always transient; in some cases it persisted in a marked manner for as long as counts continued to be made which was usually for 3 days, and there was then nothing to suggest that it would not continue indefinitely. This is regarded as permanent antagonism.

Boric acid is strongly antagonistic to sulphathiazole as is shown in table IV. Boric acid in concentrations of

concentration at, say, 2 hours after an intravenous dose would repay investigation

An even simpler test of comparable value may be obtained by comparing the count opposite the neck with that opposite the thigh. In Graves's disease, the thyroid rapidly takes up radio iodide from that circulating through the rest of the body. The thyroid count therefore becomes abnormally high and the thigh count abnormally low, so that the ratio between the two is greatly increased. When the value of this ratio—for example 1 hour after the dose—is compared with the value of the thyroid clearance in different subjects (fig. 7) it is seen that this "neck to thigh ratio," which can be determined in a few minutes, correlates closely with the thyroid clearance, which requires an hour for its estimation. The test is convenient for clinical use in other ways: it requires only a small radio iodine dose, 8 microcuries (μC) being enough for an estimation, whereas we use 30 μC for a thyroid clearance, and the size of this dose need not be accurately standardised, since the result of the test depends on a ratio between counting rates. This test does not involve blood samples or the collection of urine specimens, and the result may be known within an hour of first seeing the patient. At the same time it is more liable than the thyroid clearance rate to be disturbed by extraneous factors, such as thigh size, thyroid position relative to the counter, and variability in the delay of radio iodide absorption from the stomach if the dose is given orally, and the dose should therefore be given to a fasting patient or by intravenous injection. Under these circumstances the test gives, within a few minutes, information which appears to be of considerable diagnostic value in cases suspected of thyroid overactivity.

It appears, therefore, that several simple if indirect measures of the thyroid's avidity for iodine may be derived from measurements of urinary, plasma, or external body counting rates. Where such tests are used in the diagnosis of hyperthyroidism and give an equivocal result, the thyroid clearance rate is more likely to be conclusive, since it measures this rate of iodide uptake directly. And in so far as the rate of iodide uptake corresponds to the rate of output and utilisation of thyroxine, the thyroid clearance rate should measure the state of the body thyroxine metabolism. More direct information on the thyroxine phase of the iodine cycle can, however, be obtained with radio iodine and by considering the circulation of radio iodine through the body, and its acceleration in Graves's disease.

(To be concluded)

" a remarkable change has come over agriculture in all the more advanced countries of the world during the last 100 years. In former ages (and still today in the Balkans and in India) every field of wheat contained thousands of quite different plants, every orchard contained many different trees. Today there are fewer different kinds of wheat or apples in the whole of England than there were formerly in one field or one orchard. Today each of these kinds lasts long and spreads far. Genes, Plants, and People*. London: George Allen & Unwin 1950.

SYNERGISM AND ANTAGONISM AS DISPLAYED BY CERTAIN ANTIBACTERIAL SUBSTANCES

JOSEPH W. BIGGER

M.D., Sc.D. Dublin, F.R.C.P., F.R.C.P.I.

PROFESSOR OF BACTERIOLOGY, TRINITY COLLEGE, DUBLIN

It has already been shown (Bigger 1944, 1946, 1947) that two antibacterial substances may display either synergism with or antagonism to one another when acting on bacteria in a culture medium.

This paper records the results of an investigation undertaken to determine the interaction of several antibacterial substances when tested in pairs against *Bacterium coli* in a synthetic medium. Such a medium was used in preference to broth because one of the substances to be investigated was sulphathiazole, and broth, even after treatment by Harper and Cawston's (1945) method, contains sulphonamide antagonising substances which are not present in the synthetic medium used. The medium, which was a modification of one described by Gale (1947) had the following composition:

Glucose	30 g
Ammonium phosphate ($(\text{NH}_4)_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$)	5.0 g
Sodium chloride	1.0 g
Ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$)	0.3 g
Magnesium sulphate ($\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$)	0.7 g
Potassium dihydrogen phosphate	0.5 g
Dipotassium hydrogen phosphate	5.0 g
Water to	1000 ml.

pH adjusted to 7.5

As a result of precipitation of phosphates occurring during heating, the concentrations of iron, magnesium, and phosphate in the medium used were considerably lower than stated in the formula.

The strain of *Bacterium coli* used in the investigation grew rapidly and well in this medium, but, for reasons which will be dealt with in another paper, 'Lab. Lemmon' was added to the medium to give a final concentration of 1 in 20,000.

The substance or substances under investigation were dissolved in the medium, the pH of which, after the addition, was in all cases adjusted to 7.5. Serial dilutions were made in 5 ml volumes of the medium contained in small bottles covered with loosely fitting aluminium caps.

Bottles were inoculated by adding to each one drop from a Dreyer pipette of a suitable dilution in buffered saline of a 24 hour culture of the organism grown in the medium. The bottles were incubated at 37° and were examined daily for 3 days. The naked eye appearance of the medium was recorded as:

- C = Clear
- T = Slight to moderate turbidity
- TT = Marked to full turbidity

One loopful (5 mm loop) from each culture which had remained clear was spread over the surface of an agar slope which was incubated. The colonies which developed were counted. It was possible to count up to several hundred colonies on a slope. When the number was too great to permit accurate counting, the growth was recorded as:

- + = Colonies uncountable
- ++ = Confluent growth

No great accuracy is claimed for this method of estimating the number of living bacteria in a culture, but it has the advantage over other methods of economy of time, material, and apparatus. It is of considerable value to be able to estimate, even if without a high degree of accuracy, the number of living bacteria in a culture which may contain up to several million living bacteria per millilitre without detectable loss of clarity.

DEFINITIONS

here are not, so far as I am aware, any universally pted definitions of the terms synergism and antagon in the sense in which they are used in this paper, and re going further, I must define them

Then two antibacterial substances acting together, in a specified concentration for a specified time and er specified conditions on a certain number of teria, reduce the number to a lower level than does h of the substances acting alone in the concentration which it was present in the mixture and under the e conditions, the two are said to act synergistically. Synergism should be distinguished from the potentia 1 which a substance which is not itself antibacterial y exercise on an antibacterial one

When two antibacterial substances acting together a specified time under specified conditions on a tain number of bacteria, fail to reduce the number to ower level than does one of the substances acting ne in the concentration in which it was present in the xtire and under the same conditions, the second stance is said to behave antagonistically to the first

RESULTS

The investigation was confined to a study of substances—sulphathiazole, penicillin, streptomycin,

Chloromycetin* (chloramphenicol), boric acid, and the sodium salt of *p* aminosalicylic acid—acting in pairs in Lemco synthetic medium on *Bact. coli*

It is unnecessary to state in detail the results given by he fifteen combinations a few examples will suffice. The method of presentation is illustrated in table I, which shows the synergistic action of penicillin and sulphathiazole. The bottles of Lemco synthetic medium, containing penicillin or sulphathiazole, or both, in the concentrations shown, were so inoculated that each gave 24 colonies per loop. After incubation for 22 hours, one loopful of each was spread over an agar slope. The number of colonies which developed on incubation are recorded in the table

The bottom line gives the number of bacteria which survived the action of penicillin alone in the concentra tions shown in the top line. The right hand column

gives the number of bacteria which survived the action of sulphathiazole alone in the concentrations shown in the left hand column. The rest of the table shows the number of bacteria which survived the combined action of penicillin and sulphathiazole. Penicillin alone, in a concentration of 16 units per ml, permitted the bacteria to grow sufficiently to give rise to heavy turbidity. Sulphathiazole alone, in a concentration of 1/4 mg per 100 ml, permitted 95 bacteria per loop to survive. The combination of the two substances in the same concentrations yielded a count of 0 per loop.

Table II shows another example of synergism—between streptomycin and sulphathiazole. The combination of 1/8 mg streptomycin per 100 ml and 1/8 mg sulphathiazole per 100 ml yielded 1 colony, as compared with uncountable colonies with the same concentration of sulphathiazole alone and heavy turbidity with the same concentration of streptomycin alone. Synergism in this case is marked, for the count of 1 is less than was yielded by four times the concentrations of streptomycin or of sulphathiazole alone.

In some cases, one of the two substances was found to act synergistically with the other at one range of concentrations and antagonistically to it at another. Table III shows this double action of chloromycetin in relation to sulphathiazole. Chloromycetin in a concentration of 1/4 mg per 100 ml acted synergistically with sulphathiazole in concentrations of 1/16 and 1/64 mg

per 100 ml, but antagonistically to it in concentrations 16, 4, and 1 mg per 100 ml. It should be noted that these were the results at the end of 20 hours' incubation. When incubation was prolonged to 72 hours, the antagonism gave place to synergism. In such cases as this, the antagonism is regarded as transient.

Antagonism was by no means always transient. In some cases it persisted in a marked manner for as long as counts continued to be made, which was usually for 3 days, and there was then nothing to suggest that it would not continue indefinitely. This is regarded as permanent antagonism.

Boric acid is strongly antagonistic to sulphathiazole as is shown in table IV. Boric acid in concentrations of

concentration at, say, 2 hours after an intravenous dose would repay investigation

An even simpler test of comparable value may be obtained by comparing the count opposite the neck with that opposite the thigh. In Graves's disease, the thyroid rapidly takes up radio iodide from that circulating through the rest of the body. The thyroid-count therefore becomes abnormally high and the thigh count abnormally low, so that the ratio between the two is greatly increased. When the value of this ratio—for example 1 hour after the dose—is compared with the value of the thyroid clearance in different subjects (fig. 7) it is seen that this "neck to thigh ratio," which can be determined in a few minutes, correlates closely with the thyroid clearance, which requires an hour for its estimation. The test is convenient for clinical use in other ways: it requires only a small radio iodine dose, 8 microcuries (μC) being enough for an estimation, whereas we use 30 μC for a thyroid clearance, and the size of this dose need not be accurately standardised, since the result of the test depends on a ratio between counting rates. This test does not involve blood samples or the collection of urine specimens, and the result may be known within an hour of first seeing the patient. At the same time it is more liable than the thyroid clearance rate to be disturbed by extraneous factors, such as thigh size, thyroid position relative to the counter, and variability in the delay of radio iodide absorption from the stomach if the dose is given orally, and the dose should therefore be given to a fasting patient or by intravenous injection. Under these circumstances the test gives, within a few minutes, information which appears to be of considerable diagnostic value in cases suspected of thyroid overactivity.

It appears, therefore, that several simple if indirect measures of the thyroid's avidity for iodine may be derived from measurements of urinary, plasma, or external body counting rates. Where such tests are used in the diagnosis of hyperthyroidism and give an equivocal result, the thyroid clearance rate is more likely to be conclusive, since it measures this rate of iodide uptake directly. And in so far as the rate of iodide uptake corresponds to the rate of output and utilisation of thyroxine, the thyroid clearance rate should measure the state of the body thyroxine metabolism. More direct information on the thyroxine phase of the iodine cycle can, however, be obtained with radio iodine and by considering the circulation of radio iodine through the body, and its acceleration in Graves's disease.

(To be concluded)

A remarkable change has come over agriculture in all the more advanced countries of the world during the last 100 years. In former ages (and still today in the Balkans and in India) every field of wheat contained thousands of quite different plants, every orchard contained many different trees. Today there are fewer different kinds of wheat or apples in the whole of England than there were formerly in one field or one orchard. Today each of these kinds lasts long and spreads far. This is a wonderful world for the seedsman and the trader and, at first sight, for the cultivator as well. They all like a standard article. But it is a still more wonderful world for the diseases. The disease organism, whether it is a scale insect, a rust fungus, or a virus, no longer needs by its own adaptations to fit a key to every one of a million different locks. When it fits one it fits them all. How different is the case as I described it in nature where the plant or animal is continually selected to resist to disease, continually adapts itself, and exists in unlimited variety reproduced anew every year. Now the dice are loaded against the product of plant breeding. Perfection multiplied, standardized and invariable, is bound hand and foot, helpless to defend itself against the variable and resourceful attacker.—C. D. DARLINGTON, *F.R.S. SYNERGISM AND ANTAGONISM DISPLAYED BY CERTAIN ANTIBACTERIAL SUBSTANCES

JOSEPH W. BIGGER

M.D., Sc.D. Dublin, F.R.C.P., F.R.C.P.I.

PROFESSOR OF BACTERIOLOGY, TRINITY COLLEGE
DUBLIN

It has already been shown (Bigger 1944, 1947) that two antibacterial substances may display synergism with or antagonism to one another acting on bacteria in a culture medium.

This paper records the results of an investigation taken to determine the interaction of several bacterial substances when tested in pairs against *B. coli* in a synthetic medium. Such a medium is in preference to broth because one of the substances investigated was sulphathiazole, and broth, even treatment by Harper and Cawston's (1945), contains sulphonamide antagonising substances. These are not present in the synthetic medium used, which was a modification of one described by Gale (1947) had the following composition:

Glucose	34
Ammonium phosphate ($(\text{NH}_4)_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$)	54
Sodium chloride	14
Ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$)	0.5
Magnesium sulphate ($\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$)	0.5
Potassium dihydrogen phosphate	0.5
Dipotassium hydrogen phosphate	54
Water to	10

pH adjusted to 7.5

As a result of precipitation of phosphates occurring on heating, the concentrations of iron, magnesium, and phosphate in the medium used were considerably less than stated in the formula.

The strain of *Bact. coli* used in the investigation grew rapidly and well in this medium, but, for reasons which will be dealt with in another paper, 'Lab. Lem.' was added to the medium to give a final concentration of 1 in 20,000.

The substance or substances under investigation were dissolved in the medium, the pH of which, at the time of addition, was in all cases adjusted to 7.5. Serial dilutions were made in 5 ml. volumes of the medium contained in small bottles covered with loosely fitting aluminium foil.

Bottles were inoculated by adding to each one from a Dreyer pipette of a suitable dilution in 1 ml. saline of a 24 hour culture of the organism grown in the medium. The bottles were incubated at 37°C. and examined daily for 3 days. The naked eye appearance of the medium was recorded as:

- C = Clear
- T = Slight to moderate turbidity
- TT = Marked to full turbidity

One loopful (5 mm. loop) from each culture which remained clear was spread over the surface of an agar slope which was incubated. The colonies developed were counted. It was possible to count several hundred colonies on a slope. When the count was too great to permit accurate counting, the result was recorded as:

- + = Colonies uncountable
- ++ = Confluent growth

No great accuracy is claimed for this method of estimating the number of living bacteria in a culture, but it has the advantage over other methods of estimation of time, material and apparatus. It is of considerable value to be able to estimate, even if without a high degree of accuracy, the number of living bacteria in a culture which may contain up to several million bacteria per millilitre without detectable loss of clarity.

ts synergistically with P A S , for synergism, according the definition, requires the combination to give a lower unt than is given by each of the two substances acting one, and this was not the finding in this experiment rom the data presented in this table we cannot conclude at sulphathiazole and P A S act synergistically, but it appens that the next table presents a convincing monstration of synergism between the two

Table VII shows the results obtained when solutions of lphathiazole and of *p* aminosalicylic acid were succes vely diluted separately and together in the culture edium

The results obtained with mixtures of the two sub ances show some differences from those obtained with mixtures of boric acid and sulphathiazole At high concentrations of P A S (from 2 to $\frac{1}{2}\%$) and sulphathiazole rom 16 to 4 mg per 100 ml) the former is antagonistic o the latter At low concentrations of the two (from $\frac{1}{32}\%$ P A S and $\frac{1}{4}$ mg sulphathiazole per 100 ml ownwards) the two act synergistically Unlike boric cid, P A S exercises some effect in concentrations too ow to enable its direct antibacterial effect to be demon trated This might obviously be of considerable importance in therapeutics, but, for our present purpose, the importance of this experiment is that it proves that the antagonism of *p* aminosalicylic acid to sulphathiazole is physiological and not chemical.

Table VIII summarises the findings in this investigation It is so arranged that, when we wish to know what action one substance has on another, we trace the column under the name of the first substance downwards The action is shown where the column intersects the line extending from the name of the second substance. For example, sulphathiazole acts synergistically with *p* aminosalicylic cid, where *p* aminosalicylic acid may act either antagonistically to or synergistically with sulphathiazole

In fourteen of the fifteen combinations, synergism—which must, as has already been explained, be mutual—was demonstrated In few, however, were its effects as marked or as permanent as in the examples illustrated in tables I and II

In two cases of antagonism (chloromycetin to sulphathiazole and *p* aminosalicylic acid to streptomycin), the antagonism which was obvious for the first day or two was replaced by synergism within three days In three cases (boric acid to sulphathiazole, boric acid to penicillin, and *p* aminosalicylic acid to sulphathiazole) the antagonism, which was strong, appeared also to be permanent In two of three cases it was possible to demonstrate

S = Synergism

synergism at the same time as antagonism, although not in very marked form and over rather narrow ranges of concentrations which, of course, differed from those showing antagonism In only one case (boric acid and sulphathiazole) was antagonism strong, mutual, and permanent

DISCUSSION

There is no great difficulty in advancing hypotheses to explain synergism If the two substances interfere with the same constituent, cellular structure or metabolic process, they might be expected, in combination, to display an additive effect such as would be secured by increasing the concentration of one or other of the substances If, however, the point of attack is different, such organisms as had survived the action of the first substance would become exposed to that of the second and, if susceptible to it, would succumb In this case much more than a merely additive effect might result

Antagonism is much more difficult to explain There may be some significance in the fact that, in the three examples of marked and permanent antagonism discovered, the antagonist was either boric acid or *p* aminosalicylic acid, both markedly bacteriostatic substances* and the substance against which antagonism was displayed was either sulphathiazole or penicillin, slowly acting antibacterial substances, permitting, if not requiring, bacteria susceptible to their action to multiply for several generations before being affected by them It is suggested that, either as a result of or in association with the slowing down of the rate of bacterial multiplication for which the bacteriostatic is responsible, some alteration in the cellular structure or metabolic processes of the bacteria occurs As a result of this alteration, the other substance is either prevented from entering the cell or, having entered it, is unable to act in the manner which, in a normal cell, is responsible for its death

Apart from their theoretical interest and the light they may throw on the mode of action of antibacterial substances, are the examples of antagonism and synergism which have been discovered of any practical importance?

As regards synergism, it should be of value to know whether two antibacterial drugs may be administered simultaneously By the combination of two, it may be possible to obtain the required effect with a dosage of one which, if it alone were used, would be insufficient but which, in higher dosage, would have undesirable side-effects A more important advantage of using two drugs in place of one is the probability that this procedure would tend to prevent the multiplication of mutants resistant to one of the drugs That this is not merely a theoretical advantage is shown by the successful use of *p*-aminosalicylic acid in preventing the development of resistant strains of *Mycobacterium tuberculosis*

$1/4$ and $1/8\%$ together with sulphathiazole in concentrations falling from 4 to $1/16$ mg per 100 ml, yielded much higher counts than did the same concentrations of sulphathiazole acting alone. Since the presence of boric acid reduced the antibacterial action of sulphathiazole, boric acid is antagonistic to sulphathiazole. This table does not show any combination in which the presence of sulphathiazole reduced the antibacterial action of boric acid, and, if this were the only experiment in which the interaction of the two substances had been investigated, we would be forced to conclude that, while boric acid is antagonistic to sulphathiazole, sulphathiazole is not antagonistic to boric acid. In the next table, however, there is one point at which definite, although not pronounced, antagonism of sulphathiazole to boric acid is shown, and other experiments prove that such antagonism exists. So, in the case of boric acid and sulphathiazole, the antagonism is mutual, although that of boric acid against sulphathiazole is much greater than is that of sulphathiazole against boric acid. In all the fifteen combinations studied, this is the only example of mutual antagonism encountered. In all other cases of antagonism, one substance was antagonistic to the second but the second was not antagonistic to the first. The interaction of boric acid and sulphathiazole is unique in another respect. Despite many experiments in which the two substances were combined in various proportions, no instance of synergism was observed. In all other cases where antagonism was demonstrated, synergism could also be demonstrated when the two substances were present in different proportions.

It is not difficult to think of two antibacterial substances which, when acting together in suitable proportions, would be devoid of antibacterial properties. One could, for example, render broth so acid by the addition of hydrochloric acid and so alkaline by the addition of sodium hydroxide that, in either case, bacteria introduced would be rapidly killed. The addition of the two substances together to broth would produce sodium chloride and water, neither of which has antibacterial properties. Dilution of the combination would not, therefore, yield a product possessing such properties. Hydrochloric acid and sodium hydroxide would appear to be antagonistic, but their antagonism is chemical and not physiological and might better be described as incompatibility.

Is the basis of the antagonism of boric acid to sulphathiazole chemical or physiological? An experiment, the

results of which are shown in table V, was devised to answer this question.

Solutions of boric acid, of sulphathiazole, and of the two together in the same concentrations as in the separate solutions, were made in the medium. The three solutions were diluted in the usual way in the medium, inoculated equally with *Bact. coli*, and incubated for 44 hours, at the end of which period the number of living bacteria present was determined.

The results with boric acid are shown in the left hand column and the results with sulphathiazole in the right hand column. The middle column shows the results with the mixture of the two. At any level in the middle column, the concentration of boric acid present is the same as at the same level in the left hand column and of sulphathiazole the same as at the same level in the right hand column.

The results with boric acid alone and with sulphathiazole alone require no comment, but those given by the two together appear, at first sight, devoid of any pattern. Closer consideration, however, shows that they are capable of logical explanation. The first two zeros were due to the bactericidal action of boric acid in both concentrations. The next count, 11, which is higher than that given by the same concentrations of boric acid and sulphathiazole separately, was due to the mutual antagonism of the two. The next two counts, 50 and 7, which are higher than the corresponding counts given by sulphathiazole alone but lower than those for boric acid alone, were due to the antagonism of boric acid to sulphathiazole. The two zeros following are due to the bactericidal action of sulphathiazole uninfluenced by

TABLE VI

boric acid which, at these levels ($1/16$ and $1/32\%$), was in too low concentration to exercise any antagonistic effect. Subsequent counts are not significantly different from the corresponding results with sulphathiazole alone.

This experiment presents a curious paradox. It is possible to prepare in a culture medium a mixture of two antibacterial substances, such as $1/4\%$ boric acid and 16 mg sulphathiazole per 100 ml, which is more effective in killing bacteria when diluted 1 in 8 than it is when undiluted. The chief importance of the experiment, however, is that it proves that the antibacterial action of sulphathiazole was not significantly altered by having been in contact for some time with boric acid. The antagonism of boric acid to sulphathiazole is, therefore, physiological and not chemical.

The most striking example of antagonism encountered in the investigation was that of p aminosalicilic acid (P A S) to sulphathiazole which is shown in table VI. P A S in a concentration of 2% was antagonistic to sulphathiazole in concentrations ranging from 4 to $1/16$ mg per 100 ml. At lower concentrations of P A S, its range of antagonism to sulphathiazole was reduced, but even at $1/8\%$ its antagonism was marked. The fact that the count with, for example, $1/4\%$ P A S and 1 mg sulphathiazole per 100 ml was lower than with $1/4\%$ P A S alone, does not entitle us to state that sulphathiazole

s synergistically with P A S, for synergism, according to the definition, requires the combination to give a lower unit than is given by each of the two substances acting alone, and this was not the finding in this experiment on the data presented in this table we cannot conclude that sulphathiazole and P A S act synergistically, but it appears that the next table presents a convincing demonstration of synergism between the two.

Table VII shows the results obtained when solutions of sulphathiazole and of *p* aminosalicylic acid were successively diluted separately and together in the culture medium. The results obtained with mixtures of the two substances show some differences from those obtained with mixtures of boric acid and sulphathiazole. At high concentrations of P A S (from 2 to 1/2%) and sulphathiazole (from 16 to 4 mg per 100 ml) the former is antagonistic to the latter. At low concentrations of the two (from 0.2% P A S and 1/4 mg sulphathiazole per 100 ml upwards) the two act synergistically. Unlike boric acid, P A S exercises some effect in concentrations too low to enable its direct antibacterial effect to be demonstrated. This might obviously be of considerable importance in therapeutics, but, for our present purpose, the importance of this experiment is that it proves that the antagonism of *p* aminosalicylic acid to sulphathiazole is physiological and not chemical.

Table VIII summarises the findings in this investigation. It is so arranged that, when we wish to know what action one substance has on another, we trace the column under the name of the first substance downwards. The action is shown where the column intersects the line extending from the name of the second substance. For example, sulphathiazole acts synergistically with *p* aminosalicylic acid, where *p* aminosalicylic acid may act either antagonistically to or synergistically with sulphathiazole.

In fourteen of the fifteen combinations, synergism—much must, as has already been explained, be mutual—was demonstrated. In few, however, were its effects as marked or as permanent as in the examples illustrated in tables I and II.

In two cases of antagonism (chloromycetin to sulphathiazole and *p* aminosalicylic acid to streptomycin), the antagonism which was obvious for the first day or two was replaced by synergism within three days. In three cases (boric acid to sulphathiazole, boric acid to penicillin, and *p* aminosalicylic acid to sulphathiazole) the antagonism, which was strong, appeared also to be permanent. In two of three cases it was possible to demonstrate

S = Synergism

synergism at the same time as antagonism, although not in very marked form and over rather narrow ranges of concentrations which, of course, differed from those showing antagonism. In only one case (boric acid and sulphathiazole) was antagonism strong, mutual, and permanent.

DISCUSSION

There is no great difficulty in advancing hypotheses to explain synergism. If the two substances interfere with the same constituent, cellular structure or metabolic process, they might be expected, in combination, to display an additive effect such as would be secured by increasing the concentration of one or other of the substances. If, however, the point of attack is different such organisms as had survived the action of the first substance would become exposed to that of the second and, if susceptible to it, would succumb. In this case much more than a merely additive effect might result.

Antagonism is much more difficult to explain. There may be some significance in the fact that, in the three examples of marked and permanent antagonism discovered, the antagonist was either boric acid or *p* aminosalicylic acid, both markedly bacteriostatic substances,* and the substance against which antagonism was displayed was either sulphathiazole or penicillin, slowly acting antibacterial substances, permitting, if not requiring, bacteria susceptible to their action to multiply for several generations before being affected by them. It is suggested that, either as a result of or in association with the slowing down of the rate of bacterial multiplication for which the bacteriostatic is responsible, some alteration in the cellular structure or metabolic processes of the bacteria occurs. As a result of this alteration, the other substance is either prevented from entering the cell or, having entered it, is unable to act in the manner which, in a normal cell, is responsible for its death.

Apart from their theoretical interest and the light they may throw on the mode of action of antibacterial substances, are the examples of antagonism and synergism which have been discovered of any practical importance?

As regards synergism, it should be of value to know whether two antibacterial drugs may be administered simultaneously. By the combination of two, it may be possible to obtain the required effect with a dosage of one which, if it alone were used, would be insufficient but which, in higher dosage, would have undesirable side-effects. A more important advantage of using two drugs in place of one is the probability that this procedure would tend to prevent the multiplication of mutants resistant to one of the drugs. That this is not merely a theoretical advantage is shown by the successful use of *p* aminosalicylic acid in preventing the development of resistant strains of *Mycobacterium tuberculosis*.

* See note at end of article

in the body of a patient undergoing treatment with streptomycin

As regards antagonism, it is improbable that boric acid would ever be prescribed for systemic treatment in such a dose as to render its antagonism to sulphathiazole or penicillin dangerous. This is not so, however, of local applications or of solutions introduced into cavities. The danger may not be very great, but caution suggests the inadvisability of combining in any form boric acid with sulphonamides or with penicillin. The antagonisms of chloromycetin to sulphathiazole and of *p* aminosalicylic acid to streptomycin are weak and transient and are, therefore, not likely to be of importance. The antagonism of *p* aminosalicylic acid to sulphathiazole, which is strong and permanent, requires serious consideration. This antagonism, as table VI shows, occurs in its most marked form with 2% P.A.S. When the concentration of P.A.S. is reduced to 1/8% antagonism is scarcely demonstrable. It will be seen from table VII that, when the concentration of P.A.S. is lowered to 1/32% or less, it behaves synergistically with sulphathiazole. The maximum concentration of P.A.S. attainable in the human body is considerably less than 1/32%, and there is therefore no possibility of antagonism between P.A.S. and sulphathiazole occurring during treatment of a patient.

My general conclusion is that, as regards the six substances investigated, the synergism which, with a single exception, occurs between them might be of considerable value and the antagonism which has been demonstrated in a few cases is very unlikely ever to represent a real danger.

SUMMARY

1 The antibacterial action of six substances—sulphathiazole, penicillin, streptomycin, chloromycetin, boric acid, and *p* aminosalicylic acid—acting in pairs on *Bact. coli* in a synthetic medium was studied.

2 Synergism was demonstrated in the case of every combination except one.

3 Antagonism was demonstrated in the case of five combinations. In only three cases was it marked and permanent, and in only one of these (boric acid and sulphathiazole) was each substance antagonistic to the other.

4 The theoretical and practical importance of the findings are discussed.

NOTE

The words bacteriostatic and bacteriostatic which are used in this paper are neologisms. They are derived from the modern Latin *bacterium* and the classic Latin *freno*—I bridle, curb, restrain, or check. A bacteriostatic is a substance which restrains the multiplication of bacteria. This word is advanced as it more accurately represents the action of many substances which have hitherto been described as bacteriostatic. No chemical substance is known which, in the presence of a culture medium, and under conditions suitable for their growth, holds the number of bacteria constant, and therefore no substance can strictly be said to have a bacteriostatic action. Many substances, including boric acid, and *p* aminosalicylic acid, to which the term is applied in this paper, have a bacteriostatic action.

It is a pleasure to record the great help given to me in this investigation by Mr George Ware, B.A., and to thank the Medical Research Council of Ireland for a grant to him which enabled me to avail myself of his valuable services. I thank also my colleagues and the staff of my department for all their assistance.

'Cortisone' (a glucocorticoid) all produce eosinopenia when injected into normal people (Forsham et al. 1948, Recant et al. 1948, Thorn and Bayles 1949). In patients with Addison's disease glucocorticoids will still produce eosinopenia whereas adrenaline and A.C.T.H. will not. This suggests that the eosinopenia following the administration of adrenaline or A.C.T.H. results from the liberation of glucocorticoids from the adrenal cortex.

This action on the eosinophils has been used (1) as a check on the activity of A.C.T.H. during therapeutic trials, (2) as a measure of adrenal cortical function in the diagnosis of Addison's disease, and (3) as a screening test for substances suspected of having A.C.T.H. like

ivity (Spies and Stone 1949) the processes involved in the action of circulating eosinophils are not known.

We decided to study this effect of adrenaline further and compare with that of ephedrine. Ephedrine was chosen because its pharmacological action is similar to that of adrenaline and continued administration to patients could be easier because the effects of each dose last longer and because it is active by mouth. It is obvious that a substance which causes eosinopenia will not necessarily behave in other respects like cortisone, and conversely a substance which does not produce eosinopenia is not necessarily devoid of these properties.

METHOD

The subjects were inpatients with pulmonary tuberculosis in a fairly static condition, afebrile, and either waiting or undergoing collapse therapy. For twelve hours beforehand, and during the test, they remained in bed, and took only water by mouth. On the morning of the test, an initial eosinophil count was performed immediately afterwards the test substance was administered, and counts were then made every two or four hours until the completion of the test.

Oxalated venous blood was used for all determinations, which were made by Dunger's direct method with eosin (see Forsham et al 1948, and for the statistical aspects Discombe 1946) except that blood was drawn to the 1 mark in the white cell pipette, instead of the 0.5 mark, giving a dilution of 1 in 10. At first, two pipettes and four double-cell Neubauer haemocytometers were used for each determination (one pipette being used to fill four cells). The eosinophils in 8 large squares of each cell were computed (i.e., a total of 64 squares or 6.4 c.mm., equivalent to 0.64 c.mm. of blood). The accuracy of this method varies with the square root of the number of cells counted, and the error in enumerating small numbers of cells was found to be large. We later used four pipettes and four double-cell Fuchs Rosenthal counting chambers (i.e., a total of 25.6 c.mm., equivalent to 2.56 c.mm. of blood), and this modification gave more consistent results.

Each of 22 subjects received 5 minims of 1 in 1000 adrenaline subcutaneously. From these, 6 subjects were selected, in most of whom the eosinopenia following adrenaline was pronounced, and these on another occasion were given ephedrine gr 1 (except case 17, who

Changes in eosinophil counts in 6 subjects after an injection of distilled water (con) or adrenaline (adr), or an oral dose of ephedrine (eph)

received gr $\frac{1}{2}$) by mouth. As controls, on another day, 13 subjects (including 5 of the 6 subjects mentioned above) were each given 5 minims of sterile distilled water subcutaneously.

Note—Records of eosinophil counts should give details of the method of counting used, for minor variations in technique may lead to misleading results. In carrying out this screening test it is also highly desirable to make observations on several subjects, each of whom should be given, on different occasions, the standard substance (in this case adrenaline), an inert material as a control (e.g., distilled water), and the test substance (in this case ephedrine).

RESULTS

Distilled Water—Under basal conditions, the eosinophil counts of the 13 controls, over six hours, ranged from +13% to -30% of the initial level (table I).

Adrenaline—After 5 minims of 1 in 1000 adrenaline subcutaneously, the eosinophil counts of the 22 subjects at four hours ranged from +2% to -78% (table II). This response seems too variable to be useful in the diagnosis of Addison's disease, but the contrary view is expressed by Thorn and Forsham (1949). The discrepancy may be attributable to the fact that the volunteers on which our observations were made were not normal healthy people.

Ephedrine—In the dosage used, ephedrine caused a significant eosinopenia (varying from -41% to -71%) in all 6 subjects tested. The findings in these subjects after the three different injections, are compared in the figure and in table III.

TABLE III—EOSINOPHIL COUNTS IN 6 SUBJECTS AFTER SUBCUTANEOUS INJECTIONS OF DISTILLED WATER (CONTROLS) AND OF ADRENALINE (5 MINIMS OF 1 IN 1000) AND SINGLE DOSES OF EPHEDRINE BY MOUTH

The differences between the adrenaline and ephedrine figures and the controls (last column) were analysed by means of Student's *t* test. Case 17 was excluded because control figures were not available. The adrenaline and ephedrine figures both differ significantly from the controls, the values of *P* being less than 0.01 in each case.

in the body of a patient undergoing treatment with streptomycin

As regards antagonism, it is improbable that boric acid would ever be prescribed for systemic treatment in such a dose as to render its antagonism to sulphathiazole or penicillin dangerous. This is not so, however, of local applications or of solutions introduced into cavities. The danger may not be very great, but caution suggests the inadvisability of combining in any form boric acid with sulphonamides or with penicillin. The antagonisms of chloromycetin to sulphathiazole and of *p* aminosalicylic acid to streptomycin are weak and transient and are, therefore, not likely to be of importance. The antagonism of *p* aminosalicylic acid to sulphathiazole, which is strong and permanent, requires serious consideration. This antagonism, as table VI shows, occurs in its most marked form with 2% P.A.S. When the concentration of P.A.S. is reduced to 1/8% antagonism is scarcely demonstrable. It will be seen from table VII that, when the concentration of P.A.S. is lowered to 1/32% or less, it behaves synergistically with sulphathiazole. The maximum concentration of P.A.S. attainable in the human body is considerably less than 1/16%, and there is therefore no possibility of antagonism between P.A.S. and sulphathiazole occurring during treatment of a patient.

My general conclusion is that, as regards the six substances investigated, the synergism which, with a single exception, occurs between them might be of considerable value and the antagonism which has been demonstrated in a few cases is very unlikely ever to represent a real danger.

SUMMARY

1 The antibacterial action of six substances—sulphathiazole, penicillin, streptomycin, chloromycetin, boric acid, and *p* aminosalicylic acid—acting in pairs on *Bact. coli* in a synthetic medium was studied.

2 Synergism was demonstrated in the case of every combination except one.

3 Antagonism was demonstrated in the case of five combinations. In only three cases was it marked and permanent, and in only one of these (boric acid and sulphathiazole) was each substance antagonistic to the other.

4 The theoretical and practical importance of the findings are discussed.

NOTE

The words bacteriostatic and bacteriostatic which are used in this paper are neologisms. They are derived from the modern Latin *bacterium* and the classic Latin *freno*—I bridle, curb, restrain, or check. A bacteriostatic is a substance which restrains the multiplication of bacteria. This word is advanced as it more accurately represents the action of many substances which have hitherto been described as bacteriostatic. No chemical substance is known which, in the presence of a culture medium, and under conditions suitable for their growth, holds the number of bacteria constant, and therefore no substance can strictly be said to have a bacteriostatic action. vity (Spies and Stone 1949) processes involved in the action of circulating eosinophils are not known.

We decided to study this effect of adrenalin further and compare it with that of ephedrine. Ephedrine was chosen because its pharmacological action is similar to that of adrenalin and consequent administration to patients would be easier because the effects of each dose last longer and because it is active by mouth. It is obvious that a substance which causes eosinopenia will not necessarily behave in other respects like cortisone, and conceivably a substance which does not produce eosinopenia is not necessarily devoid of these properties.

METHOD

The subjects were inpatients with pulmonary tuberculosis in a fairly static condition, afebrile, and either waiting or undergoing collapse therapy. For twelve hours beforehand, and during the test, they remained in bed, and took only water by mouth. On the morning of the test, an initial eosinophil count was performed immediately afterwards the test substance was administered, and counts were then made every two or four hours until the completion of the test.

Oxalated venous blood was used for all determinations, which were made by Dunger's direct method with eosin (see Orsham et al 1948, and for the statistical aspects Discombe 1946), except that blood was drawn to the 1 mark in the white cell pipette, instead of the 0.5 mark, giving a dilution of 1 in 10. At first, two pipettes and four double-cell Neubauer semicountometers were used for each determination (one pipette being used to fill four cells). The eosinophils in 8 large squares of each cell were computed (i.e., a total of 64 squares or 6.4 c.mm., equivalent to 0.64 c.mm. of blood). The accuracy of this method varies with the square root of the number of cells counted, and the error in enumerating small numbers of cells was found to be large. We later used four pipettes and four double-cell Fuchs Rosenthal counting chambers (i.e., a total of 256 c.mm., equivalent to 2.56 c.mm. of blood), and this modification gave more consistent results.

Each of 22 subjects received 5 minims of 1 in 1000 adrenalin subcutaneously. From these, 6 subjects were selected, in most of whom the eosinopenia following adrenalin was pronounced, and these on another occasion were given ephedrine gr 1 (except case 17, who

Changes in eosinophil-counts in 6 subjects after an injection of distilled water (con) or adrenalin (adr), or an oral dose of ephedrine (eph).

received gr $\frac{1}{2}$ by mouth. As controls, on another day, 13 subjects (including 5 of the 6 subjects mentioned above) were each given 5 minims of sterile distilled water subcutaneously.

Note.—Records of eosinophil counts should give details of the method of counting used, for minor variations in technique may lead to misleading results. In carrying out this screening test it is also highly desirable to make observations on several subjects, each of whom should be given, on different occasions, the standard substance (in this case adrenalin), an inert material as a control (e.g., distilled water), and the test substance (in this case ephedrine).

RESULTS

Distilled Water—Under basal conditions, the eosinophil-counts of the 13 controls, over six hours, ranged from +13% to -30% of the initial level (table I).

Adrenalin—After 5 minims of 1 in 1000 adrenalin subcutaneously, the eosinophil counts of the 22 subjects at four hours ranged from +2% to -78% (table II). This response seems too variable to be useful in the diagnosis of Addison's disease, but the contrary view is expressed by Thorn and Forsham (1949). The discrepancy may be attributable to the fact that the volunteers on which our observations were made were not normal healthy people.

Ephedrine—In the dosage used, ephedrine caused a significant eosinopenia (varying from -41% to -71%) in all 6 subjects tested. The findings in these subjects after the three different injections, are compared in the figure and in table III.

TABLE III—EOSINOPHIL-COUNTS IN 6 SUBJECTS AFTER SUBCUTANEOUS INJECTIONS OF DISTILLED WATER (CONTROLS) AND OF ADRENALINE (5 MINIMS OF 1 IN 1000) AND SINGLE DOSES OF EPHEDRINE BY MOUTH

Case no.	Drug	Eosinophils per c.mm				Change (% of initial level)			
		Initial	2 hr	4 hr	6 hr	2 hr	4 hr	6 hr	Max

	Ephedrine gr 1	376	269	198	245	-28	-47	-35	-47

The differences between the adrenalin and ephedrine figures and the controls (last column) were analysed by means of Student's *t* test. Case 17 was excluded because control figures were not available. The adrenalin and ephedrine figures both differ significantly from the controls—the values of *P* being less than 0.01 in each case.

The effect of ephedrine would perhaps be expected, since this drug may act, at least in part, by virtue of its anti-amine oxidase action, which would preserve adrenaline liberated at adrenergic nerve endings. In view of its greater stability, ephedrine would probably be superior to adrenaline as a standard in this type of investigation, while supplies of A C T H for this purpose remain limited.

It is possible that the therapeutic action of ephedrine in allergic conditions is partly due to the release of A C T H.

SUMMARY

The effect on the eosinophil count of ephedrine given by mouth has been compared with that of subcutaneous injections of adrenaline and of distilled water. Ephedrine produced a significant eosinopenia.

The limitations of the method in screening tests for cortisone substitutes are defined.

It is suggested that ephedrine could be employed as an alternative standard while A C T H remains scarce.

Our thanks are due to Dr G. E. Beaumont, Dr C. A. Keele, and Dr J. G. Scadding for advice and encouragement, to the Pathology Department, Brompton Hospital, and Messrs Hawksley and Sons for laboratory facilities, and to the patients for their co-operation.

HÆMOPHILUS INFLUENZÆ MENINGITIS

REPORT OF FIVE CASES

JAMES SANDILANDS

M.B. Edin., M.R.C.P.E.

MEDICAL REGISTRAR, CAMBORNE REDRUTH MINERS' AND GENERAL HOSPITAL

Of the six cases of non-tuberculous meningitis admitted to this small general hospital in just over two years, five have been due to *Hæmophilus influenzae*. This relatively high incidence has not been noted in other hospitals in Cornwall, including the isolation hospital. At each of three comparable hospitals single cases only have been seen in the same period. No connecting factor was noted between the Camborne cases, which occurred at wide intervals.

Bousvert (1948), in the U.S.A., showed that the incidence of *H. influenzae* in the nasopharynx tends to be familial, though the case incidence of meningitis due to this organism was not familial in distribution. Ounsted (1949) noted that his cases tended to be drawn from large families in which there were several siblings older than the patient, and he suggests (Ounsted 1950) that this may be typical of *H. influenzae* meningitis, inferring that passage of the organism through these siblings may heighten its virulence. Large families were not noteworthy in the present series. No studies of siblings were attempted, but *H. influenzae* was found in a throat swab from a parent in one case.

Harnes and Mitman (1947) stated that *H. influenzae* meningitis was the most common form of meningitis admitted to the Children's Hospital, Boston, U.S.A., 1933-36, when meningococcal meningitis was not

epidemic. Ounsted (1949) considers that the absolute as well as the relative incidence of *H. influenzae* meningitis may have increased. This also seems likely from figures published by Braid and Meyer (1949). The reason for this change in relative incidence as compared with meningococcal meningitis may very well be the use of sulphonamides in the febrile illnesses met with in general practice. These drugs would tend to abort the meningococcal infection in its septicaemic phase, and the greater resistance of *H. influenzae* may explain why there has been no similar fall in the incidence of this infection. Thus, in three of the cases described below, preliminary treatment with penicillin and/or sulphonamides before the meningitic stage did not seem to abort the condition. The reports cited, although they suggest an increased incidence, are not conclusive, and more information is required.

CASE RECORDS

Case 1—A boy, aged 1 year, was admitted on July 14, 1947, having been listless and anorexic for three days before. There was no relevant past or family history.

On examination (not seen by me) he was restless, apathetic, and feverish, with a temperature of 101.8°F. There was obvious meningism, and his reflexes were brisk. The cerebrospinal fluid (c.s.f.) was turbid and under a pressure of 300 mm., and contained sugar 18 mg. per 100 ml., 5,000 polymorphs per c.mm., and Pfeiffer's bacilli.

Treatment—The patient was given 20,000 units of penicillin intrathecally every day and 50,000 units intramuscularly six hourly plus sulphamerazine by mouth to a total of 6 g. a week.

Progress—Three days after the start of treatment the child's temperature fell to normal and he seemed improved, but the c.s.f. still contained nearly 3000 cells and some Pfeiffer's bacilli. The intrathecal dose of penicillin was reduced to 10,000 units and then to 5000 units daily. After a further eight days there was thought to be some improvement in his general condition and his meningism and rigidity were less pronounced, but his temperature was rising, and he did not take his feeds well and vomited. Next day he was blind, with pupils which reacted only slightly to light, severe meningism, and spastic limbs. Penicillin 50,000 units was administered intracranially and 10,000 units by lumbar puncture. On the same evening the child had a convulsion. On July 27 he died.

Necropsy showed influenzal bronchopneumonia and a meningeal exudate at the base and over the vertex, especially the frontal region. The ventricles were free from infection.

Case 2—A boy, aged 12 years, was admitted on March 31, 1948, having been out of sorts for two weeks (later his mother said he had had a head injury). His initial complaint was vomiting with pain in the right iliac fossa, present for a week, and headache. There was no relevant family or past history.

On examination he had a furred tongue, no abdominal distension, but deep tenderness in the right iliac fossa with some guarding, and tenderness in the left iliac fossa. No other abnormalities except a slight cough were noted. His temperature was 98.8°F.

Treatment was begun with sulphadimidine ('Sulphamethine') by mouth and 30,000 units of penicillin every three hours intramuscularly.

Progress—Next day the boy's temperature was 104°F and he complained of headache and had a harsh loose cough. Cerebration seemed to be impaired, and he was grinding his teeth. A few purpuric spots were seen on the abdominal wall, the throat was red and mucopus was seen in the nasopharynx. Tenderness was noted over the maxillary and frontal sinuses. There was neck rigidity, with a positive Kernig's sign and extensor plantar responses. The c.s.f. was accidentally contaminated with blood, and the pressure was not read but it contained less than 5 cells per c.mm. and no organisms. The sugar content was 75 mg. per 100 ml.

On the third day the fever was less, but meningism was still present. The ears appeared healthy. The c.s.f. pressure was 165 mm., with the same pathological findings. The blood white-cell count was 15,000 per c.mm., predominantly polymorphs. Dr N. S. Alcock, the neurologist saw him that day, found no meningism and thought the condition was not intracranial.

By the fifth day the boy's fever had subsided and he seemed much better, with no meningism, but slept a lot. A chest rogram was clear, but both antra and frontal sinuses were opaque. Nothing abnormal was found in the urine. There was a leucocytosis of 16,000 per c.mm., but a blood culture was negative on April 7. The patient remained fairly well, and his temperature did not rise above 99°F, except for an occasional spike to 100°F.

On April 13, two weeks after admission, he had twitching of the right side of his face, was drowsy, vomited, and was continent of urine and faeces afterwards. Next day the c.s.f. was clear, under normal pressure, with 55 cells per c.mm. (mononuclears), sugar 75 mg per 100 ml, protein 1 mg per 100 ml, and no organisms in film or culture. The ophthalmologist reported that the optic fundi were normal.

By April 15 the patient was much worse, being semicomatose with sluggish pupils, and his fever reappeared (104°F). The neurologist examined him next day when a right hemiplegia had developed. He thought the case was possibly one of tuberculous meningitis but did not consider there was any indication for transference to a neurosurgical unit. The patient died on April 17.

Necropsy revealed a purulent meningitis encapsulated over the left cerebral hemisphere. Both ethmoidal sinuses contained yellow pus containing *H. influenzae*, as did the meningeal pus. There was no evidence of a fractured skull. The bowel contained many specimens of *Ascaris lumbricoides*.

Case 3—A boy, aged 1 year, was admitted on April 18, 1948, having been listless, irritable, and holding his head as if in pain for six days. He now had a little diarrhoea, also as his past health and family history were not relevant.

On examination he was a well nourished child, flushed, and with superficial scalp veins standing out prominently. He looked mentally alert and resented interference, holding his head with his hands. His temperature was 102°F. No definite physical signs were found, and meningism was absent. Next day the findings were the same, but there was slight evidence of meningism. The c.s.f. was slightly turbid, under a pressure of 290 mm, and contained 700 cells per c.mm. (polymorphs), with sugar less than 20 mg per 100 ml, and many *H. influenzae* (Pittman's type B).

Treatment was begun with sulphadiazine by mouth, penicillin 30,000 units intramuscularly three hourly, and 25,000 units intrathecally. From a study of the available published reports it seemed that a larger single intrathecal dose might cause convulsions, but further information indicated that this applied only to the cruder penicillins.

Progress—After three days the child's appearance had not changed but his temperature was falling. On the fourth day the c.s.f. was clear and pressure normal, and two days later the cell-count had fallen from 4000 to 360 per c.mm. and no growth was obtained on culture. Fever had subsided, and the child's general condition was fair. Sulphadiazine was stopped because of temporary anuria after five days, but was started again on April 27 and continued until May 3. Throat swabs from the child grew *H. influenzae*, but those from the parents were negative. He remained well, with no exacerbation of fever, but there was a transient slight reappearance of Pfeiffer's bacilli in the c.s.f. on May 3, with a rise in the cell-count from normal to 200 per c.mm. The skin on the child's back was breaking down and he had had a full course of sulphadiazine, so all specific treatment was stopped on May 4, when the c.s.f. was once more sterile. The c.s.f. remained sterile with the cell-count (mononuclears) raised to 20 per c.mm. until May 29, when the count was less than 5 per c.mm. The child now appeared completely normal.

Follow-up—When seen one and two months later the child seemed well, with no abnormalities of behaviour. Seen again a year later he was quite normal.

Case 4—A girl, aged 13 months, was admitted on May 31, 1948, having had vomiting and fever for three weeks. She had had convulsions three weeks ago, but these were discounted because her father was an epileptic. One red and bulging ear-drum was said to have been seen at the time. Sulphonamides had been given and seemed to improve her. In the past week she had deteriorated and developed neck rigidity and vomiting.

On examination she was a well nourished but irritable child, with obvious neck rigidity, sluggish pupillary reaction to light deviation of the eyes to the right, and left facial

weakness. No signs of otitis were seen. Her temperature was 99°F. The pressure of c.s.f. was not read, only a few drops being collected, but it contained 960 cells (polymorphs) per c.mm., sugar 6 mg per 100 ml, and many *H. influenzae*.

Treatment was begun with 'Soluthiazole' intramuscularly and penicillin 25,000 units intramuscularly three-hourly and 50,000 units intrathecally daily.

Progress—On the third day there was obvious head-retraction and retraction of eyelids. The eyes were deviated to the right, with left hemiparesis, and absent light reflex in the left pupil. The child seemed almost blind. There was no change next day, and, though fever was low, the c.s.f. remained infected, with a high cell count, and there was clearly a partial block. Treatment was continued by the cisternal route, from whence specimens of c.s.f. were less xanthochromic but also infected. c.s.f. from the cisterna magna became sterile on the eighth day, but the cell-count was high and the child's clinical condition had deteriorated. She died on the twelfth day.

Necropsy showed both middle ears healthy. There was purulent basal meningitis with thick greenish pus round the chiasma, the pons, the base of the cerebellum, and the spinal cord, with many adhesions round the foramen magnum. The lateral ventricles were very dilated with turbid c.s.f. and flakes of greenish pus.

Case 5—A boy, aged 7 months, was admitted on Oct. 9, 1949, having apparently had pain in the left side of his head with fever and diarrhoea, for the previous week. His brother had had a febrile illness with whitlows two weeks before. The patient was just being weaned when his illness began. He cried a lot on Oct. 5 and had rigors. He held the left side of his head and tended to turn it to the left. He was thought to have a left otitis media and was treated by his own doctor with penicillin to a total of 250,000 units. The diarrhoea cleared but it reappeared, with blood streaking, on the day of admission.

On examination he was a well nourished child, with no definite abnormalities except the fleeting suggestion of a left internal squint. There was no meningism, and his ears were healthy. An X ray film of his chest showed clear lung fields. His white-cell count was 33,000 per c.mm. (polymorphs 68%).

Progress—Next day (Oct. 10) the boy had a convulsion in the evening. There was still no meningism, and the fontanelle and sutures were not bulged or separated, but he rolled his head about as if in pain. The c.s.f. was cloudy, under increased pressure and contained 3000 cells per c.mm., with no sugar, and elongated gram-negative bacilli, later identified as *H. influenzae*, were found.

Treatment—Penicillin and sulphadiazine treatment was begun intramuscularly, but the penicillin was stopped next day, and streptomycin begun in a dosage of 75 mg intrathecally and 0.75 g intramuscularly each day. Meningism was definite three days after admission.

Further course—After three days treatment the child was improved, alert, and recognised his parents. His c.s.f. was sterile, but the cell count was still high. Temperature 100–101°F. On the seventh day of treatment streptomycin was reduced to 50 mg intrathecally and 0.5 g intramuscularly daily, and next day the fever had gone and the child was well. Intrathecal treatment was stopped on the tenth day. By the seventeenth day the child was still very well and active in his cot, but he seemed to hold his back stiffly. Since there was no neck rigidity or Kernig's sign, this may have been due to the trauma of lumbar puncture. All treatment was stopped. On Nov. 2 there had been no deterioration. The c.s.f. was sterile but contained 55 cells per c.mm. with 90 mg of protein per 100 ml.

On Nov. 7, the cells in the boy's c.s.f. numbered 44, and on Nov. 14, 22 per c.mm. He was thriving and was discharged, to be reviewed later.

DISCUSSION

The prodromal period in the present cases was as variable as in those described by Zinnemann (1946), Braid and Meyer (1949), and Ounsted (1949). The variability of the presenting symptoms, which has been noted elsewhere, was present to some degree in this small series. However, head pain was present in 3 cases, and otitis media was suspected, wrongly as it turned out, in 2 of these. Convulsions occurred in the early stages in

2 cases Localising signs of nervous involvement were present in only 1 case (case 4) on admission. It was noteworthy that meningism, as shown by a positive Kernig's sign and neck rigidity, was present on admission in only 2 cases, both ultimately fatal, the prodromal period was short in one of them and long in the other. This indicates the chief diagnostic difficulty. Diarrhoea was noted in 2 cases at an early stage, and the abdominal pain in case 2 was a "red herring," later supposed to be due to ascariasis.

It therefore seems that the practitioner is faced with the same problem here as in the early diagnosis of tuberculous meningitis, without the help of a significant contact history which is so often present in the tuberculous cases. That the admission of the patient to hospital, however, may not at once clarify the diagnosis is exemplified by case 2, who showed transient meningism at an early stage but with a normal C.S.F. He was seen by a neurologist next day and again later and was thought not to have any intracranial disease.

Blood culture has produced a positive diagnosis in many cases in an early stage, but in the one case in which this would have been useful (case 2) it was done after penicillin and sulphonamide therapy were begun and may have been negative for that reason. The C.S.F. was extremely misleading because, even when the cell-count rose the fluid was sterile and the cells were mononuclears. This type of case must be extremely rare but, since it seems to be eminently curable by modern methods, it deserves further consideration. In only 1 case were the bacilli typed and here (case 3) they were Pittman type B. The sugar in the C.S.F. was much reduced or absent in all cases except case 2, where it was normal even in the terminal stage.

The question of surgical aids to diagnosis in cases of meningitis has been discussed by Cairns (1949). Perhaps few would agree that neurosurgical facilities are necessary at all hospitals treating meningitis, but, since modern methods have given hope in previously hopeless cases, such possibilities must be considered. Sampling of the ventricular fluid would certainly have revealed the diagnosis in case 2, and ventriculography might exclude intracranial tumour or abscess in doubtful cases where it might be dangerous to proceed too hurriedly with intrathecal antibiotics. Cairns (1949) recommends the ventricular route in treatment in all cases where signs of intrathecal blocking are present after use of the lumbar route. He points out the dangers of the cisternal route in cases with severe head retraction. An example of this was case 1. One feels that cases 1 and 4 might have responded to ventricular antibiotics. This treatment also may avert a long term result such as that quoted by Cairns and described by Baker (1934), when a girl of 17 died of hydrocephalus resulting from a meningococcal meningitis in infancy. The long term results of modern treatment of meningitis have still to be observed.

Other adjuncts to chemotherapy and antibiotics are heparin and air, which seems to have been discarded, and streptokinase (Cathie 1949). One would like to hear more of the latter. Specific antiserum seems to be no longer necessary. Gaisford (1949) emphasises the importance of a massive initial dosage of streptomycin. Ounsted (1949), on the other hand, recommends dosage on the lines suggested by the Medical Research Council and adjusted to the patient's clinical response, streptomycin was used thus in case 5 and the baby rapidly recovered but after two months he has a C.S.F. cell count of 22 per cmm, though otherwise well. The results achieved in Ounsted's series seem to justify this method, and, with the short course of streptomycin given, the question of resistance will probably not arise in the average case, although this criticism of the treatment is

offered by Braid and Meyer (1949) and Wilson (1948). Penicillin, although less rapid in its action, would always be available for treatment of the resistant case.

Some observers have described a high recovery rate with no intrathecal treatment, on streptomycin and sulphonamides, usually sulphadiazine (Hoyne and Brown 1948), but, with complicated cases such as cases 1, 2, and 4, it seems obvious that something more is required, probably surgical assistance or perhaps streptokinase or a similar agent intrathecally.

Several observers have noted the satisfactory mental development of recovered children, in spite of the considerable inflammation and scarring which must at one time have been present. The 2 recovered cases in this series are certainly normal children, but 1 has been observed for only a very short period. The passage of years may possibly show some late results from scarring in cases where a block has apparently been successfully circumvented.

SUMMARY

A relatively high local incidence of *H. influenzae* meningitis is noted.

Cases are described, including one of particularly obscure nature.

The difficulties of diagnosis are considered and modern views on treatment discussed.

My thanks are due to Dr L. W. Hale and Dr R. H. Blair for their helpful criticism and permission to publish these cases.

SUDDEN DEATH OF YOUNG ATHLETE FROM RUPTURE OF ASCENDING AORTA

ERNST JOEL

M.D. Breslau

RESEARCH OFFICER, DEPARTMENT OF EDUCATION, ARTS,
AND SCIENCE, PRETORIA

R. H. MACKINTOSH

L.R.C.P.E.

PATHOLOGIST, SOUTH AFRICAN POLICE MEDICO-LEGAL
LABORATORIES, JOHANNESBURG

A WELL BUILT athlete, aged 15, returned from a gymnastic class during which he had indulged in weight lifting and wrestling. On reaching home he collapsed with a vice like pain in the chest and died within an hour.

NECROPSY FINDINGS

The young man was 5 ft 8 in. tall and weighed 141 lb. His musculature was strong and general development good, but sexually he was retarded.

Heart—The pericardium was tense and bluish and contained 150 ml. of coagulated blood and 650 ml. of fluid blood and hemorrhagic serum. The left ventricle was dilated and hypertrophied, being twice the normal size. No fibrous patches were noted in the myocardium. The foramen ovale was closed. All three cusps of the aortic valves were present. The ductus arteriosus was patent and filled with a fresh thrombus.

Aorta—The isthmus of the aorta was so narrow that it admitted only a fine metal sound. Above the stenotic part the aorta was considerably dilated, forming a flaccid aneurysm.

nal bag which bulged towards the right side. There was a tear 3 cm long in the lateral wall of this bag, starting just above the aortic valves and establishing a communication between the lumen of the aorta and the pericardium. The internal mammary arteries were much enlarged, their calibre corresponding to that of radial arteries of normal adult males. Below the stenosis the aorta was about half the normal width. Its walls were abnormally thin. No arteriosclerosis or atheroma was noted.

Lymphatic Tissue.—A persistent thymus gland, weighing 38.4 g, with active Hassall's corpuscles was found. There was an abundance of lymphatic tissue, especially in the spleen and the mesentery. Large lymphatic plaques were noted in the mucosa of the small intestine.

DISCUSSION

This case was characterised by the presence of multiple congenital anomalies of the cardiovascular system, of which the stenosis of the isthmus of the aorta is the most important. This stenosis formed a mechanical obstruction, which explains the considerable dilatation of the aorta above the isthmus, the compensatory overdevelopment of the internal mammary arteries, and the hypertrophy of the left ventricle. There were present a persistent thymus gland with active Hassall's corpuscles, hypoplastic thin walled arteries, and a general abundance of lymphatic tissue. The immediate cause of death was rupture of the ascending aorta.

The deceased had been a first class athlete and, though he was sexually underdeveloped, neither his general bodily growth nor his physical efficiency had been retarded by the congenital disease which caused his premature death. This observation, however, is not unique. Bonnet (1903) has pointed out that, in the presence of isthmus stenosis, collateral circulation may completely compensate for the central defect. Hart (1920) has published a case of sudden death in a man, aged 41, who before his fatal collapse could do strenuous physical labour. Necropsy revealed complete obliteration of the isthmus, thrombo endocarditis of a two-cusped aortic valve, mesoarteritis syphilitica of the thoracic portion of the aorta, and hypertrophy of the left ventricle. Above the obliterated isthmus the aorta showed a "balloon like" enlargement.

The question arises as to what part the weight lifting and wrestling played in causing the fatal tear of the aorta. No doubt the physiological rise in blood pressure invariably accompanying activities of this kind must have exerted a deleterious influence (Jokl 1947).

A similar observation was reported by Wasastjerna (1903) concerning a boy, aged 13, who collapsed while skating. Jores (1924) emphasised the general significance of physical effort in cases of rupture of the aorta in persons with stenosis of the aortic isthmus and ventricular hypertrophy. He said that, provided a good collateral circulation was established, exercise would not cause a rupture unless there was aneurysmal enlargement of the aorta and abnormal thinness of the artery walls. Contrary to what may be expected, arteriosclerosis is usually not present in cases of this kind, though the elastic elements of the artery walls are as a rule affected.

The condition is rare, among 5000 necropsies conducted between 1900 and 1905 by the Vienna Medico Legal Institute, only 4 instances of advanced stenosis of the aortic isthmus were encountered. A good general discussion of this question can be found in the textbook of Henke and Lubarsch (1924).

 INFIRMARY AT LEEDS, LECTURER ON DISEASES OF THE SKIN
 IN THE UNIVERSITY OF LEEDS

The aetiology of progressive lipodystrophy is unknown. Hartston (1933), reviewing the published cases and reporting two new ones, said that the onset often followed an acute specific fever. He referred to the association of changes indicating sympathetic disturbance, such as trophic changes in skin and nails, pigmentation, acrocyanosis, and abnormal perspiration.

Thomson (1936) described a case of segmental atrophy of fat of subcutaneous tissues, which Parkes Weber regarded as a variety of deep scleroderma.

Weber and Bode (1930) reported facial lipodystrophy associated with unerupted central incisor teeth in a child and manifest first at the age of 4½ years. They emphasised that the affection was not necessarily progressive, and regarded it as a congenital developmental abnormality.

An endocrine origin has been suggested, and cases have been reported in which thyrotoxicosis (Ziegler 1928, Marañon and Blanco Soler 1926), myxoedema (Christiansen 1922, Alquer and Humbert 1922), pituitary dysfunction (Christiansen 1922), and diabetes (Ziegler 1928) have been present. Zalla (1920) described a patient in whom the pituitary gland was found at necropsy to be compressed and flattened and the sella turcica enlarged.

Discussing a case presented by Cockayne (1932) Parkes Weber questioned whether such fat atrophy might not depend on basophilic hypopituitarism, since fat hypertrophy, according to the work of Cushing, might depend on basophilic hyperpituitarism.

The association of progressive lipodystrophy with changes in the central nervous system has been reported by several workers. Perutz (1932) suggested a relationship between lipodystrophy and lesions in the mid brain. Sarbo (1921) described a girl, aged 16, with typical symptoms of involvement of the striate body following encephalitis contracted in the epidemic of 1920; there was rapid emaciation of the face and upper half of the body, but the hips were so enlarged by abnormal deposit of fat that she could not put on her old skirts. Pollak (1930) described one patient who also showed choreo-athetoid movements. Klien (1921) noted progressive lipodystrophy after cerebral concussion. Maslov (1930) reported a case which he attributed to a cerebral lesion. The patient, a woman aged 38, had chronic rheumatoid polyarthritis and epidemic encephalitis; there was great accumulation of fat on the lower trunk, and she was 5 ft ¼ in tall and measured 52 in round the hips. Ewserowa (1929) reported the case of a woman of 30 in whom the onset of progressive lipodystrophy coincided with the development of Jacksonian epilepsy. Radiography showed a hyperostosis extending upwards from the back of the sella turcica.

In the following two cases, personality changes suggested possible nervous factors in the aetiology of the disease.

CASE RECORDS

Case 1.—A married woman, aged 47, was one of seven children. There was no family history of lipodystrophy, epilepsy, or other significant illnesses and she had had no previous illness of note. Her first pregnancy occurred at

the age of 26, and her second at 42. Menstruation returned normally after each pregnancy and was still regular. The lipodystrophy probably started at the age of 28, after the birth of the first child. No sudden change was noted, the condition developing gradually. The patient could not say whether or not the condition spread from above downwards. Major epilepsy started a few months after the birth of her first child. It is not known whether the lipodystrophy preceded the fits, but the two conditions started about the same time. Fits have been experienced regularly, with no period of freedom longer than a few weeks, and there has been no aura. The fits commonly occur during menstruation. They have been observed in hospital and consist of a sudden loss of consciousness, no typical tonic and clonic phases have been observed, but the patient has often been incontinent and has often injured herself. Loss of consciousness lasts 2 or 3 minutes and is followed by confusion, stupor, and aggression lasting a few hours. The patient has not been under regular treatment.

The patient attended the dermatological outpatient department of the General Infirmary at Leeds in June, 1947, with a few months' history of typical lupus erythematosus over the bridge of the nose.

On examination loss of subcutaneous fat affected the face, arms, and trunk to the pubes and was fairly well demarcated across the buttocks at the level of the greater trochanter. Below this the subcutaneous fat appeared to be normal. The photograph (fig. 1) does not show the line of transition clearly, but it was readily appreciated by pinching up folds of skin above and below the line of demarcation. The face had the typical sunken appearance of progressive lipodystrophy (fig. 2). Apart from the loss of subcutaneous fat the skin appeared normal in texture, and hair distribution was normal. No other abnormalities were found. The blood pressure was 160/90 mm Hg. There was no albumin in the urine, nor any reducing substances when tested with Benedict's reagent. The blood Wassermann reaction was negative. Blood cholesterol levels were total cholesterol 297 mg per 100 ml, free cholesterol 125 mg per 100 ml, and ester cholesterol 172 mg per 100 ml. The proportion of esterified cholesterol was 58%. A glucose tolerance test showed a "lag" or "steep" curve.

Specimen	Blood sugar (mg per 100 ml)	Urine sugar
0	93	0
1 (½ hr)	250	0
2 (1 hr)	218	—
3 (1½ hr)	137	0
4 (2 hr)	73	0

Lumbar puncture was refused.

Radiography of the skull showed no abnormality. Electroencephalography showed no abnormality either at rest or on overbreathing. There was a good medium voltage normal alpha rhythm of 9 per sec, which was symmetrical.

Progress.—Shortly after the patient came under observation she became confused, aggressive, and unmanageable and was admitted to Menston Mental Hospital. Her mental condition has not improved, and she is reported as being dull, querulous, and self-centred, showing dissatisfaction with her position and general treatment. She is inclined to interfere in the affairs of others, occasionally

becomes aggressive and violent towards patients and nurses and has to be nursed in a single room. She has made several attempts at suicide. Here epileptic fits occur with an average frequency of four a month. During the past year the line marking the junction between the normal subcutaneous fat and the lipodystrophic area has moved from across the buttocks at the level of the greater trochanter to a line lying in the crease between buttocks and thighs. It is unusual for fat atrophy to affect buttocks and lower legs in progressive lipodystrophy. There has been a little improvement in the lupus erythematosus but this condition is still present.

Case 2.—A boy, aged 11 years, had been normal to the age of 6 years, when some teeth were removed, after which his face became thin in a few weeks. The rest of his body was similarly affected later, but recently his legs have "put out" a little, according to his parents. He was extremely timid, troublesome at school, difficult with playmates, moody and restless at home. A brother, an idiot, suffered from choreiform movements and double incontinence, and not walk or speak, and was admitted at the age of 4 years to a mental institution, where he died two years later from bronchopneumonia. Two other brothers, aged 7 years and 2½ years, were alive and well.

On examination there was much wasting from loss of fat affecting the face very much and the trunk moderately (fig. 3). No other abnormality was found on inspection.

Radiography of the skull, pituitary fossa, arms and legs, and chest showed no abnormalities.

Blood.—The blood picture was normal and a Wassermann reaction was negative.

Electroencephalography showed very little of the normal alpha activity and some excess of slow-wave activity over both hemispheres. This type of abnormality is regarded as non-specific and is found in normal persons, epileptics, and psychopaths, and even sometimes with cerebral tumours.

Fig. 3—Progressive lipodystrophy (case 2), showing gross wasting of face and moderate involvement of trunk.

DISCUSSION

It seems that the association of progressive lipodystrophy with endocrine and nervous disorders is more than a coincidence. The association of changes in the central nervous system has led to the suggestion that lesions of the mid brain may cause progressive lipodystrophy. Klien (1921) and Christensen (1922) put forward the view that disturbances of the endocrine system and of the autonomic nervous system may act reciprocally. Beznak and Hasch (1937) have shown that, when the sympathetic supply to an area is cut, the deposition and mobilisation of fat in that area is retarded. de Langen (1938) brings forward considerable evidence in favour of the nervous control of fat metabolism through a centre in the mid brain. The serum lipid level increases greatly with large doses of barbiturate, but those narcotics which seem to act on the cortex rather than the mid-brain do not produce this effect. Section of the cord below the third thoracic vertebra in rabbits prevented this rise in serum lipids level.

Fig. 2—Typical appearance of face in progressive lipodystrophy (case 1).

after administration of 'Veronal' de Langen also showed that the administration of anterior pituitary extract to animals caused an increase in serum lipoids, whereas administration of posterior pituitary extract caused a decrease. On the basis of this work it is tempting to speculate that in progressive lipodystrophy a lesion or disturbance of function in the mid brain affects the subcutaneous fat through autonomic connections, and that this mid brain centre can be influenced by endocrine function.

SUMMARY

Two cases of progressive lipodystrophy are reported.

The first, a woman, developed epilepsy about the time of onset and later became psychotic.

The second, a boy, had abnormal personality traits and an abnormal electro-encephalographic record.

The association of changes in the central nervous system with progressive lipodystrophy is discussed.

We wish to thank Dr Maxwell Telling for permission to investigate and report case 2, Dr J Dawson for the blood-cholesterol investigations, Dr D Taverner for electro-encephalographic reports, Dr R H Seville for the photographs, and Dr R W Lennon for the report on the mental condition of case 1.

New Inventions

DISPOSABLE ILEOCOLOSTOMY BAGS

THE Koenig-Rutzen bag, or its English counterpart described by Hardy and his colleagues,¹ gives the patient with an ileostomy or an unreliable colostomy almost complete security from "accidents" and even minor soiling of the underwear. But the rubber bags are expensive, the special adhesive with which they are stuck to the skin is somewhat messy to apply, and cleaning them at bedtime or before catching the morning train seems a tedious job.

The ideal bag would be self-adhesive, like the Bunyan-Stannard envelopes used for burns, and so cheap that it could be discarded when soiled, like a paper handkerchief, and replaced by a new one. It must be large enough for there to be no risk of its being overfilled with faeces or (if it is gastight) with flatus, strong enough to withstand a recumbent patient's weight or the pressure of a belt, and not liable to emit embarrassing crackles when the patient leans forward to take a cup of tea.

This ideal has not yet been realised, but the bags here illustrated (fig. 1) come near it, so far as can be judged from trials on one colostomy. They are intended to be "assembled" by the patient or nurse from two components—an oblong transparent plastic bag, sealed at one end, and a square of adhesive plaster, sticky on both sides, with a one inch circular hole in the middle—as follows.

First decide whether the hole in the plaster will fit over the opening in the bowel, and if not how big it must be. Remove the gauze from one side of the plaster and stick the square on to the bag so as to leave about a quarter of an inch uncovered at the open end. Insert two fingers into the bag and cut a hole in the gauze and bag wall through the window in the plaster, enlarging it if necessary. Fold over the open end of the bag

Fig 1

Fig 2

Fig 1—Standard bag assembled. Bag is 10 in length of flexible transparent seamless plastic tubing $3\frac{1}{2}$, or 4 in wide, sealed at end. Double-faced plaster square is $\frac{1}{2}$ in narrower, to allow bag to bulge forwards. Square may be placed near middle or at sealed end of bag open end being closed with special clip.

Fig 2—Square bag applied. Standard bag can be worn vertically or horizontally; vertical bag with open end below can be emptied in situ, if necessary.

and tuck it under the plaster, leaving one corner free to provide an exit for flatus. Poke a wisp of cotton wool into this corner from below.

After a little practice all this can be done easily in five minutes, and in odd moments a little stock of bags can be assembled ready for use. When the bag is applied one has only to remove the remaining piece of gauze, insert the protruding bowel (if any) through the hole, and press the plaster firmly on the surrounding skin. In removing the bag there is usually no difficulty in peeling the plaster away from the skin, the use of benzene to loosen it sometimes causes soreness.

The standard bag will usually be worn with its long axis vertical, but for patients in bed the horizontal position, with the hole placed nearer the middle, seems preferable. A square bag (fig. 2), with the hole towards one upper corner, may be worth trying.

Some additional support for the bag will probably be needed, though in some cases two or three turns of a wide crêpe bandage will be sufficient. Where there is a tendency to prolapse, and for the more active patient, an elastic webbing belt has proved highly satisfactory, this has a plastic insertion over the colostomy and carries a modified St Mark's shield, in which a semilunar piece has been cut away from the lower edge, so that pressure is applied without obstructing the passage of faeces into the bag.

A still simpler method of fixing the bag has been tried, but cannot yet be recommended. This is by inserting a square of ordinary 3 in adhesive plaster inside the bag, cutting a small circular hole in the plaster to fit over the bowel opening, and then cutting a larger square hole in the bag wall. In this way a strip of the adhesive surface is exposed round the hole in the plaster which will hold the bag on the skin.

The standard bags, plasters, squares, clips, and supporting belts are supplied by Messrs Down Bros and Mayer & Phelps Ltd., and the designs have been largely the work of Mr Gaillard of that firm.

E CLAYTON-JONES
M.D. Camb

"In England and Wales during the year 1947, 664 children under one year of age died because their parents' blood would not mix. During that year, just over eighteen out of every 1000 children dying under the age of one year died from this cause. Further, it is likely that some hundreds of children were stillborn and some hundreds of the survivors are mentally defective for the same reason. During the same year, 523 persons of all ages died of cerebrospinal fever, 644 of measles, and only 242 of diphtheria."—Dr R N C McCurdy *The Rhesus Danger* London Heinemann Medical Books 1950.

Reviews of Books

Handbook of Diseases of the Skin

RICHARD L. SUTTON, M.D., emeritus professor of dermatology and syphilology, University of Kansas, RICHARD L. SUTTON, JR., M.D., associate professor of dermatology and syphilology in the university London Henry Kimpton 1949 Pp 749 63s

INSTEAD of revising older works by himself and his father, Dr Sutton Jr., has produced an entirely new textbook of diseases of the skin. Inevitably much of their old material has been used, but by starting afresh in this way he has produced a thoroughly up-to-date book, free from obsolete material. The illustrations and make up are first-class, and the text comprehensive. The commoner diseases are in ordinary type and the rarities in small print. The numerous references are incorporated in the text, which makes reading a little difficult, the alternative method of collecting references at the end of each section might have been more comfortable for readers. The work will be accepted as one of the leading large standard reference textbooks.

Operative Technique in Specialty Surgery

Editor WARREN H. COLE, M.D. F.A.C.S., professor of surgery, University of Illinois New York Appleton Century Crofts 1949 Pp 725

A SYMPOSIUM of articles written by such men as Smithwick, Naffziger, Meigs, Beck, and Frank Dickson, all acknowledged experts in their specialised fields, requires no 'trailer'. Plastic, thoracic, orthopaedic, neurosurgical, gynaecological, and genito urinary surgical specialties are all dealt with in great detail. The authors describe their own methods, and dwell largely on the practical aspects, but where necessary academic facts are clearly stated. The result is a book which is refreshingly vital and provocative. Experience teaches, and the authors have passed on the lessons of their specialised experience in a fascinating manner. There is not a poor article in the book, and personal interest or ignorance alone will make some sections more or less appealing. Beck's chapter on cardiac surgery, a model of lucidity, gives a wealth of information in a few pages. Meigs's chapter on gynaecology, dealing largely with the treatment of malignant disease by radical resection, will interest all general surgeons. Dickson details his methods in osteomyelitis and shows very convincing figures in favour of primary closure after sequestrectomy. In the article on prostatectomy Freyer's methods are advocated, and the claim is made that bladder mucosal "fringes" are an asset rather than a disadvantage. Fine production, printing, and illustrating help to make this a work of value to the practising general surgeon.

The Ordinary Devoted Mother and Her Baby

D. W. WINNICOTT, F.R.C.P. 1950 Pp 47 1s (From the author, 47, Queen Anne Street, London, W.1.)

Dr Winnicott has made a pamphlet of nine broadcast talks. In them he is trying to do something very difficult—to formulate experiences and feelings that are not often put into words, to try to put a finger on the numberless small observations and responses which make a success of the sensitive mother's relationship with her baby. These things are not easy to talk about or put across. The intuitive person does them unreflectingly. The insensitive person either does not know of their existence, or struggles painfully to acquire some specific skills, when what is wanted is the capacity to perceive the only just perceptible, to interpret these very faint signals and to supply whatever needs they express. Dr Winnicott is at times brilliantly successful at showing what he sets out to show, and, perhaps even more important, at showing what sort of thing he wants to show. Criticism might, however, be directed at one point of technique. This is the device of saying "you" when he means "I". For example "You know that the first object your baby loves—a bit of blanket or a soft toy—for the infant this is almost part of the self." This may be good for the suggestible, but almost certainly bad for the contra suggestible and irritating for the few who like to understand what is

being said to them. A more fundamental quarrel with Dr Winnicott's unstated assumption that parents are perfect. The good mother will, on this view, starve anything from her child, and the good father will stand a relationship in which mother and child are all in all to one another and from which he (for what, it is true, is called "a short period") is totally excluded. These expectations are contrary to experience.

All the same this pamphlet throws many flashes of light on a dark subject. Both Dr Winnicott and the British Broadcasting Corporation are to be congratulated on their courage in making this heroic effort.

Elsevier's Encyclopædia of Organic Chemistry

Editor F. RADT. Series III. *Carboisocyclic compounds*. Volume 12B. *Naphthalene and its derivatives*. Amsterdam Elsevier Publishing Company. London Cleaver Hume Press 1949 Pp 344 55s for the whole work.

IT is stated that this encyclopædia will run to 525,000 pages in about 40 parts. Vols 14, 13, and 12A have already appeared, and after 12B is completed vol 1 will follow and then the remainder in order. The present part of vol 12B deals with naphthalene and its derivatives and is itself divided into two parts. The first is concerned with the hydrocarbons—naphthalene and its hydro derivatives and derivatives of these with side-chains, while the second deals with the halogen-substituted compounds. Published work is covered up to 1944, but in addition work on the structure of compounds has been brought up to 1948. There is a subject and a formula index, references are given in lists which are easy to find, and a good point is that the structural formulae of naphthalene and tetralin, with the positions numbered, are printed at the top of each left hand page. Some practical investigations have been made to clear up discrepancies in the literature, and the results are included in this number.

Das chronische cystische Hydrom der Dura

in seinen Beziehungen zum sogenannten chronischen traumatischen subduralen Hämatom und zur Pachymeningitis hamorrhagica interna im Lichte der Reaktionen pathologie ALFRED BANNWARTH, Dozent Dr med h.c. München Stuttgart Thieme 1949 Pp 57 D.M. 9.60

THIS rather prolix monograph is an attempt to establish a common relation between the conditions known to English speaking surgeons as subdural hydroma, subdural hæmatoma, and pachymeningitis hamorrhagica interna. Dr Bannwarth first presents three cases of subdural hydroma which he has seen personally, with brief references to previous reports. He then discusses the pathology of this and the other two states, rightly emphasising that subdural hydroma may be a complication after evacuation of a subdural hæmatoma. He suggests that the three conditions are stages in one pathological process, the basis of which is pericapillary exudation within the layers of the dura, beginning as *peristatischen Hyperämie*. He believes that these conditions are an intradural reaction to trauma, toxins and other agents. Unfortunately, there are no histological illustrations to support this view, and in the absence of such evidence the thesis will not find wide acceptance among British surgeons.

Principles and Practice of Plastic Surgery

ARTHUR JOSEPH BARSKY, M.D., D.D.S. attending plastic surgeon, Beth Israel Hospital, New York London Bailière, Tindall & Co. 1950 Pp 499 75s 6d

BEFORE the war the books available on plastic surgery were few in number, and one by Dr Barsky, published in 1938, was a valuable guide to the methods then in use in the United States. He has now given us a newer and bigger book, containing almost twice as much material. An important addition is a separate chapter on the hand. The matter is well presented and the text easy to read though it is doubtful whether the division of the page into two columns is an improvement. The line diagrams are clear and pertinent, and the photographic reproductions good. Dr Barsky has described those methods of treatment that he has found most satisfactory, and this is infinitely better than a catalogue of possible methods. A sound presentation of the subject consequently emerges.

THE LANCET

LONDON · SATURDAY, JULY 8, 1950

Expensive Prescriptions

It is a fundamental principle of sickness insurance that those who have no need of the physician should pay for attention to the less fortunate, but this provides no sanction for extravagance in furnishing drugs and other material aids to treatment. There is unfortunately no magic which will entirely insulate a national service from the hard realities of the national budget, and during the past year it has been made clear that no more money can be voted for the National Health Service, and consequently that over-spending on any one of its branches will have to be offset by restriction on others. In this context, the report of the joint committee on prescribing, summarised on another page, is of interest to all concerned in the service, for there is reason to believe that money is being wasted on drugs which could be better spent elsewhere.

The committee very rightly insists that there should be no absolute ban on any kind of prescribing: the doctor must be free to prescribe whatever he thinks necessary, though on occasion he may be required to justify his action to his local colleagues. The committee decided against drawing up any black-list of proprietary or other preparations whose prescription would lead to inquiry, and it was at first dubious even about the propriety of having a list of preparations which the practitioner could prescribe without risk of questions later. In its first report, therefore, it merely recommended that a letter should be sent to doctors expressing concern at "the high cost of the pharmaceutical services, particularly where caused by the prescription of expensive brands of proprietary drugs," and asking for the co-operation of the profession to prevent excessive prescribing. But at the same time it decided (by a majority) that steps should be taken to compile a list of "approved drugs," and it now suggests that for this purpose proprietary preparations could suitably be classified into six categories. Apart from those in the two lowest, which comprise remedies of "doubtful value," it sees no medical reason why these preparations should not be freely prescribable in the National Health Service—unless they are advertised direct to the public, in which case they should not appear in N.H.S. prescriptions. Moreover "new drugs of proved value not yet standard" should be freely prescribable without reservation. But the committee, while it does not regard itself as competent to advise on the question of cost, thinks that those proprietary preparations which it regards as "not therapeutically superior to standard preparations" should be prescribable only if satisfactory arrange-

ments for price are made between the health departments and the manufacturers. The committee is prepared, if asked, to continue its work of classifying "such proprietary preparations as are referred to us" into the six categories. This arduous task would necessitate the collection of all relevant information and a study of each preparation individually—a labour recalling that of Sisyphus and of Hercules in the Augean stables.

For the sake of the service it is urgently necessary to make economies in the use of drugs, and it is obvious that a considerable saving could properly be made on proprietary preparations, which at present account for over 30% of the total cost. Undoubtedly a great many unnecessarily expensive preparations are ordered because doctors are ignorant of the official equivalents, and, though the preparation of an "approved" list has its disadvantages, it would be welcome to many practitioners as a guide. Many drug firms perform an important public service, and so long as we depend on them to develop new remedies we must not make it impossible for them to earn profits which finance the expensive research they undertake. But anyone who is anxious to see the limited funds of the N.H.S. used on essentials must be distressed by merely casual expenditure on remedies which are obtainable more cheaply under another name. It would be wrong for any practitioner to feel that he cannot prescribe what is necessary, or for any patient to fear that he will receive an inferior or ineffective drug. But the service cannot afford to waste money on names, and it is right that doctors should have their attention frequently drawn to the existence of official alternatives to many of the branded drugs which they are accustomed to prescribe. The committee's moderate report with its emphasis on reasonable persuasion, represents the right approach to a complex problem.

Intermittent Claudication

INTERMITTENT claudication is a limping or lameness which appears after walking a certain distance. It is caused by pain of a particular type, usually at first a dull ache or tightening, and becoming intense cramp like, or gripping. The patient is compelled to stop walking, but after a rest the pain wears off and he can go a further distance. LEWIS¹ and others showed conclusively that this pain is caused by the accumulation in contracting ischaemic muscle of a factor which stimulates sensory nerve-fibres. In peripheral vascular disease muscle ischaemia is produced by general arterial narrowing and by local thromboses. The site at which pain is felt depends on the muscle or muscle group which is maximally affected in relation to the work which the limb is performing. The muscles most commonly affected are those of the calf, but it is not uncommon for a patient to complain of pain in the front of the leg in the thigh, or in the foot, and in the foot it is important not to mistake pain from this cause for that from foot-strain, flat-foot, or other purely local disorders. A careful history and examination will elicit the characteristic features and time-relations of the pain, and usually other evidence of vascular insufficiency.

Prof A M BOYD and his co-workers² have given an account of their enormous experience of this disease at the peripheral vascular clinic of Manchester Royal Infirmary. They divide claudicants into three clinical types, representing three grades of severity. In type 1 the pain appears on exertion but disappears on further walking. Here the pain factor starts to accumulate and for a short time rises above the "pain threshold level", but the vessels are still capable of sufficient dilatation to remove it, and the pain passes. In type 2 the pain appears and remains at a steady level of intensity as the patient continues to walk, indicating that, once the threshold of pain has been passed, a state of equilibrium is reached in which the pain factor is removed as fast as it is formed. In type 3 very little vasodilatation is possible, and the pain increases steadily until it becomes unbearable and the patient is forced to stop. To measure accurately the distance at which pain appears, it is usually necessary to observe the patient walking, and to assess the clinical type and extent of disability, he must be exhorted to keep on walking for as long as he can. A patient who has been resting in bed for a week can often walk very much farther before he feels pain than when he has been up and about.

BOYD believes that intermittent claudication is caused by three main types of peripheral vascular disease. The commonest is "senile obliterative arteritis," or arteriosclerosis in its widest sense. Almost all arterial disease developing after the age of 35 is of this type, which is also not uncommon below the age of 30. Many cases that are labelled "Buerger's disease," or thromboangitis obliterans, are in fact cases of frank atheroma. This is not the orthodox teaching, but other workers in this field who follow up their patients carefully are coming to similar conclusions. The disease may affect principally the large or the small vessels, and secondary thrombosis may take place in the popliteal or, less commonly, in the femoral artery. The second type is primary thrombosis of the popliteal artery. This is not common—in BOYD's series it accounted for only 6 out of 472 cases of obliterative arteritis—but it is important to recognise the condition, because it is not a manifestation of generalised arterial disease with a bad prognosis for life and limb, but a purely localised traumatic phenomenon. It is found usually in men under 35 years of age and gives rise to intermittent claudication in the calf. The thrombosis starts at the point where the popliteal artery enters a fascial tunnel behind the knee joint, and spreads for a short distance up or down. It seems to result from the normal movements of the knee, sometimes without any special trauma. Arteriograms show no abnormality except in the affected segment, and no sign of inflammation is found in excised portions of the thrombosed vessel. This condition, too, is usually mistaken for Buerger's disease.

If, then, some of the cases which we commonly call "Buerger's disease" are in fact arteriosclerotic, and others are examples of primary popliteal thrombosis, can any be regarded as examples of true thromboangitis obliterans? BOYD describes eight cases of "juvenile obliterative arteritis," which, he believes, forms a third distinct group. The patients,

all men under 35, were affected in both legs. They had interdigital fungus infections and patchy phlebitis of the superficial veins. The disease started distally, causing pain, ulceration, and gangrene of the toe, and intermittent claudication in the small muscles of the feet. It spread up the legs, causing obliteration of vessels and consequent ischaemic changes, and one or both limbs were lost within 3–5 years of the onset. The pathology of this condition is not clear. BUEYER³ described certain inflammatory changes in the vessel walls, including pronounced perivascular fibrosis. BOYD, however, points out that not only are similar changes seen in and around the vessels of infected arteriosclerotic limbs, but that in juvenile obliterative arteritis the arteries above the level of the disease show little abnormality. Possibly the fungus infection of the feet, spreading up the perivascular lymphatics, accounts for the whole clinical picture. It remains to be seen what happens to these patients in the future, and we shall be interested to hear whether or not they develop lesions in the heart, the coronary or cerebral vessels, or elsewhere. Not everyone will be satisfied with BOYD's classification, because there are still cases which cannot easily be fitted into any of his three groups, and probably most people see a greater proportion of cases that do not appear to be arteriosclerotic.

Happily, in the treatment of peripheral vascular disease the emphasis has shifted from the management of gangrene to the control of early symptoms and the prevention of gangrene. In intermittent claudication the aim is to improve the blood supply of the ischaemic muscles by opening up collateral vessels. The problem, however, is not simple, and other factors must be weighed, including the clinical type, the patient's age, the nature of the arterial disease, the prognosis for life and limb, associated disease, and domestic and economic conditions. Type 1 claudicants do well with almost any method of treatment, provided their confidence is gained. In type 2 the standard procedure is lumbar sympathectomy (removing ganglia one to three), which nearly always improves the nutrition of the foot and sometimes relieves the claudication significantly. BOYD finds that 70% are able to walk one mile without pain and that the result improves with time. Not everyone would claim such good results, in particular, some patients complain that after initial improvement their pain returns. Where unilateral pain, confined to the calf, is not dispelled by sympathectomy, BOYD's operation of subcutaneous Achilles tenotomy is invaluable. The rationale is that if the tendon is divided the calf muscles are not used in walking, no pain factor is produced, and claudication does not occur. Patients quickly learn to walk without using the calf muscles, and soon can cover long distances without pain. In type 3, sympathectomy does not improve the claudication, and tenotomy is the treatment of choice, but sympathectomy is advisable as well if the limb itself is in danger. In senile obliterative arteritis the danger to life is usually greater than the danger to limb, and angina of effort, coronary thrombosis, and hypertension are contra-indications to lumbar sympathectomy. In particular if high blood pressure is lowered, thrombosis and gangrene may actually be precipitated. Nevertheless lumbar sympathectomy is now a very safe procedure.

² Boyd A M, Ratcliffe A H, Jepson R P, James G W M. *J. Surg.* 1949 31B 325

³ Buerger I. *Amer. J. med. Sci.* 1908, 136 567

and in BOYD'S series there was only 1 death in over 300 operations, both sides can be done at one time, and age alone is no contra-indication. Paravertebral sympathetic block with a 10% aqueous solution of phenol⁴ is an effective method of performing a "chemical sympathectomy," though the technique is not easy. This is a useful procedure for patients who require sympathectomy, but in whom there are contra-indications to operation. Of the various drugs which have been tried at the Manchester clinic the only one which has given encouraging results, as regards both claudication and nutrition of the leg, is vitamin E by mouth. The optimal dosage is 400 mg daily, and benefit is usually observed within 6-8 weeks. Further work is being done to assess the real value of this substance.

Peripheral Neuritis and Bronchial Carcinoma

To the many causes of peripheral neuritis another must, it seems, be added—bronchial carcinoma. In 1948 DENNY-BROWN⁵ described two cases in which these two disorders were associated, in each the neuritis was the presenting feature and the carcinoma was discovered only post mortem. In both these cases the peripheral neuritis was unusual in that the sensory elements were greatly affected, with relatively little motor involvement. Pathological examination showed extensive changes in the cells of the posterior-root ganglia with degeneration of the posterior roots and of sensory fibres in the peripheral nerves. There was little apparent change in motor fibres, but in both cases there were changes in the muscles, thought to be a primary degeneration of muscle fibres. WYBURN-MASON⁶ reported the same two cases and added a third in which the clinical involvement was motor rather than sensory and pathological examination revealed degenerative changes in the anterior roots and motor fibres of the peripheral nerves.

LENNOX and PRICHARD⁷ have now described two further instances of this strange association. In both the neurological symptoms improved for a time, but a severe relapse preceded death. Clinically, motor elements of the peripheral nerves were predominantly affected, at necropsy in one of the cases there was demyelination, chiefly of motor fibres, in selected peripheral nerves, while in the other there was no definite pathological change. The posterior-root ganglia were not examined, but severe degenerative changes are unlikely to have been present in these ganglia because the posterior columns of the cord were unaffected. LENNOX and PRICHARD found records of three further cases of bronchial carcinoma associated with peripheral neuritis, and in these three also, the presenting symptoms had been neurological.

The important question is whether this association of peripheral neuritis and bronchial carcinoma is more than accidental. DENNY-BROWN, impressed by the unusual clinical and pathological features of the peripheral nerve disorder, concluded that the two diseases were intimately connected but in the other cases that have been reported this unusual

type of sensory neuropathy has not been found, the nerve involvement being mainly of the motor element. LENNOX and PRICHARD'S cases were 5 among 299 of bronchial carcinoma, and that the association is not fortuitous is strongly suggested by their review of the incidence of peripheral neuritis in cases of carcinoma at other sites and of other types of chronic chest disease. From the pathological studies it is evident that the peripheral nerves and spinal roots have not been directly involved by neoplastic tissue, and the pathogeny of the peripheral nerve disorder remains obscure. WYBURN-MASON suggested that there was an analogy with hypertrophic pulmonary osteoarthropathy, and that the disturbance of neural function was produced "reflexly" from the lungs. DENNY-BROWN pointed out the resemblance between the posterior root ganglion degeneration in his cases and that in the ataxia of swine when these animals are fed on a diet deficient in calcium pantothenate and pyridoxine⁸, and he postulated that the cause was a metabolic disorder related to the tumour cells.

This association of diseases indicates the importance of radiography of the chest in cases of peripheral neuritis of obscure origin, and it will be interesting to study the course of the neuritis if a case is found in which the bronchial carcinoma can be removed completely.

DISSATISFIED PRACTITIONERS

LAST week the Conference of Local Medical Committees met to discuss the negotiations on general practitioners' remuneration. After emphasising that at no time, either before or since the appointed day, had agreement been reached on this subject with the Government, the conference proceeded to express its grave disquiet at the repeated hold ups and long delays in the negotiations. The Minister of Health had avoided making any definite reply when asked by the General Medical Services Committee what sum he thought should be in the central pool to implement the recommendations of the Spens report. The conference believed that he had all the data needed to make this calculation, and it pressed for an immediate statement. It was also disturbed at the suggestion, implicit in some of the correspondence with the Ministry, that future negotiations on general practitioner remuneration need not necessarily be conducted through Whitley Council machinery.

Because of its dissatisfaction with the present remuneration and with the inconclusive negotiations for its amendment, the conference proceeded to instruct the G.M.S. Committee to make preparations forthwith for the termination of contracts by general medical practitioners. It did not propose a date on which this collective termination of contracts might take place. Such a date would be fixed at another special conference, to be called if it became obvious that there was no further prospect of a satisfactory settlement. Unless a settlement is reached first, a conference will be called next December at latest.

The Minister has recently proposed to the G.M.S. Committee that he should, with the co-operation of the profession, undertake certain investigations into the actual earnings and expenses of practitioners during the year ended March 31, 1950. The conference considered this suggestion, and concluded that the chances of an

equitable settlement of remuneration might be increased by early and accurate information on practitioners' income from N H S sources, and on practice expenses. Accordingly it was willing to participate.

For the rest of its time the conference discussed and deplored the sinking status of the general practitioner, and urged the G M S Committee to do whatever it could to buttress and restore this status. Just how it was to do so did not emerge very clearly, for the conference was unwilling to admit that the loss of status was associated with, or could solely be accounted for, by the hurried and harassed form of practice that an increased load of medical and clerical duties has thrust on many doctors. It laid more stress on the gulf between the practitioner and the hospital, and felt that the practitioner should be afforded much greater clinical and administrative contact with his local hospitals and their management committees. One practical proposal came from Buckinghamshire, whose representative had been encouraged by the initial success of discussions between the Oxford Regional Hospital Board and representatives of all local medical committees in the Oxford region (see p 65). He put forward the suggestion, which was accepted by the conference, that local medical committees should themselves form a joint-committee over an area corresponding to that of a regional hospital board, and should seek through this joint committee to keep in regular touch with the board.

THE INFECTIOUS TUBERCULOUS

LIKE every other infectious disease, tuberculosis presents two problems—care of the patient, and protection of the rest of us. If it is to be brought under control, neither aspect can be ignored.¹ In our correspondence columns, Dr Grenville Mathers and Dr Trenchard note that the National Health Service Act focuses attention on treatment, and essentially on the treatment of those who can profit by it. But even this is not done well, the patient waiting for a bed may pass from the hopeful to the hopeless class before he gets so much as the chance of treatment. Moreover, as our correspondents point out, about a quarter of the pulmonary tuberculosis patients known to the chest clinics who are not in hospital have positive sputum, and they are actually discharged from sanatoria in this dangerous state, simply because there is nothing else to do with them. What becomes of them then? They do not easily find work, and if they are only to be admitted to ordinary employment on condition that they disclose their disability to their employers, as the Joint Panel on the Resettlement of the Tuberculous have recommended, they will find it hard to get a job at all. Even as it is they are apt to become derelict, the health committee of the London County Council note² that in London alone, there are at present some 160 of them living at close quarters with uninfected people in common lodging houses. The situation is intolerable for them in their sanatoria no doubt, they were taught that they were a danger to others, but what can they do about it? When society prescribes duties and withholds the means of fulfilling them, even the most law abiding transgress, as anyone who tries to park a car in London knows. These patients must be given some measure of shelter and help, not only on their own account but in the urgent interests of the whole community.

The L C C has for some time contemplated building night sanatoria in which such patients might live under medical supervision, and from which they could go out to work, perhaps under sheltered conditions. Before the Act came into force arrangements used to be made for some of them to enter small voluntary sanatoria. This was not in our view a satisfactory solution, for

such sanatoria found great difficulty in getting staff. We know of places where girls of 16½ or 16 were employed, and some of these died of tuberculosis or were crippled by it. Since the Act came into force, the regional hospital boards, according to the report of the L C C health committee, have been unable to provide accommodation for irremediably open cases, and take the view that these cases are not their responsibility. Meanwhile the health committee have been looking for suitable quarters for hostels or night sanatoria, so far without success, moreover they feel that the regional hospital board should properly be taking the responsibility, especially since a patient needing urgent treatment could be transferred to hospital much more readily if he was in a hostel controlled by the board. The job is so urgent, however, that the health committee feel it matters very little who does it as long as it gets done, and intend to send a deputation to ask the Minister of Health where the responsibility lies. They have already made one important proposal to him—namely, that St Peter's Hospital, Stepney, should be pulled down and the site used for a night sanatorium, and for industrial workshops which would be run in collaboration with the Disabled Persons Employment Corporation. The Minister was unable to approve the necessary expenditure for this project, but the need is so great that the committee intend to raise it again with him. Indeed, night sanatoria are needed throughout the country. They could receive patients who would otherwise not be discharged from sanatoria until later, and so might greatly relieve the pressure on treatment beds. If the Minister were able to arrange for the admission of tuberculous patients to a proportion of general hospital beds (p 70) this pressure might well be removed altogether, and we should have better prospects of controlling the spread of tuberculosis than we have ever had in our lives.

THE CHILD AND HIS HEREDITY

As infant deaths go down the proportion due to congenital abnormalities rises, according to Dr Fraser Roberts, speaking at the annual conference of the National Association for Maternity and Child Welfare, these now account for 1 infant death in 6, and are five times commoner as a cause of mortality than they were in 1900. In one way this is good news, because it means we are approaching the irreducible minimum—irreducible, that is, by ordinary medical, social, and eugenic measures. On the other hand, it means we are getting no nearer the prevention of such congenital defects, which are responsible not only for deaths but also for much unavoidable disability in infancy and childhood. In 1937, he said, among children of school age 37 per 100,000 were blind, a third of them from congenital defects of vision. In 1948 the incidence had fallen to 21, but two thirds of the cases were congenital in origin. If the average age of mothers could be reduced by 5 years, this incidence of congenital malformations of all kinds, he stated, would be cut by about half. Meanwhile our growing knowledge of heredity can often be used to guide those parents who have had a congenitally malformed child. In many cases it is possible to predict whether or not other children in the family are likely to be affected, and the parents can sometimes be told the exact chances against their having another defective child. Again, many malformations and abnormalities—such as hare lip or club foot—can be repaired or treated. In the case of the rhesus factor, 1 child in 150 is born with hemolytic disease, because he has inherited from his father an antigen not present in his mother, and up till 10 years ago half these children died. Now that appropriate transfusion can be begun at birth, the death rate has fallen to a tenth. It is also becoming possible to predict which people, for genetic reasons, are unduly susceptible to

ven diseases, and to ensure their protection or early treatment. Heredity is an important factor in deciding whether a person contracts tuberculosis or not, and isceptibility to rheumatic heart disease may also be redictable. Children born with a predisposition to acquire these disorders can already be protected to some extent, and as our knowledge grows we may discover how to make them proof against their opponents. He called such achievements "positive eugenics."

DICK BARTON AS A MORAL FORCE

LIKE Socrates, Dick Barton has had to face a charge of corrupting the young. Some, even, have blamed the famous radio detective for a share in the rise in juvenile delinquency—not because he favours lawbreakers (he is inveterate in the cause of right) but because he is not too particular about borrowing their methods. The charges against him have lately been investigated by the "audience research" department of the British Broadcasting Corporation, with the help of the National Association for Mental Health. Questionnaires were sent to the medical directors of 115 child guidance clinics, and 85 replies were received from some 80 clinics scattered over the country. A report on these replies was prepared by Miss Cicely de Monchaux, lecturer in psychology at University College, London. It seems that nine out of ten of those who answered had themselves heard at least one episode in the Dick Barton serial, and one was a regular listener, because—he said—an up to date knowledge of Barton's doings helped him to make touch with child patients. Only half of those replying had any evidence of the effect of the serial on children, and only a quarter thought that listening to Dick Barton made it harder for delinquents to resist temptation. A very few (6 against 76) thought there would be less delinquency if the series was brought to an end. The ultimate fate of the serial was not, on the whole, a matter of keen interest to child guidance authorities. Just over half felt that, from the standpoint of mental health, it should be discontinued or modified in some ways, but if they had to decide its fate 51 would vote for its continuation and 24 against it.

Many thought that the Dick Barton adventures supply the fantasies which children need as an emotional outlet for aggression, but in their present form they are "just an outlet." The serial might be used, it was suggested, to serve higher ends. This, however, would have to be done with a singularly light and expert touch, since children do not care for outspoken "uplift" in their entertainment any more than the rest of us. In one of Saki's tales, recently read over the air, a little girl hiding from a wolf was discovered and eaten up because her good-conduct medals clinked and gave her away—a catastrophe which the children listening to the serial thought (according to Saki) completely just. Real children are probably rather less ruthless, though they like the wicked characters (i.e., those with whom they do not identify themselves) to come to a bad end. But Saki was right in thinking they are disgusted by a prig. Most of those who listen to the Dick Barton series are aware that their hero—like Robin Hood, and other violent characters in their gallery—is, without priggishness, on the side of virtue. Only the dull are likely to miss this. Those who are antisocial already may borrow from Dick Barton, not criminal aims (of which he is free) but—possibly—criminal or violent methods. Nowadays, unfortunately, they are likely to hear of these even more freely in real life than in fiction. Theoretically it might be a mistake to reinforce ugly fact with fantasy in this way, but in practice children seem to need adventure stories much as they need vitamins. For most of them such listening is not a prelude to crime but a means of relieving tension. A parallel is to be found in

the cinema, which is often blamed for antisocial training of the young, but the departmental committee¹ which recently reported on this question did not (with one dissentient) fasten on the cinema "any primary share of responsibility for delinquency or moral laxity of children under 16." It does more harm, they thought, by providing children with a set of false values in which riches, power, luxury, or public adulation are regarded as the greatest good, and by frightening the little ones. The Dick Barton serial is also said to be too exciting for some children, and the suggestion was made that the rhythm of the episodes should not end on a crescendo, as they do at present, but should follow a low high low pattern. The audience research report remarks dryly that if, after this and other changes, Dick Barton were Dick Barton no longer, "this would appear to be a consummation which informed opinion would face with equanimity." The sentence of these judges, which amounts to letting Mr Barton off with a caution, is perhaps vitiated by the average age of the bench, a symposium of juvenile, and even better informed, opinion might have resulted in acquittal.

KHELLIN FOR CARDIAC PAIN

KHELLIN, an active principle of *Ammi visnaga* Lam, is reputed to cause active coronary vasodilatation without reducing the blood pressure or increasing the pulse rate.² This drug has lately been tested by Rosenman and his colleagues³ on 14 cases of angina pectoris, most of which had been observed for some years. Khellin ("Visammin") was given usually for 3–13 weeks, and in one case for 40 weeks. At other times a placebo was given, and at yet other times no treatment. The number of trinitrin tablets taken daily by each patient under these three different conditions was estimated. In 7 of the 14 cases the number of trinitrin tablets was substantially less with khellin than with a placebo or no treatment, and in 6 of these 7 cases capacity for exertion seemed to be increased—though this is perhaps only another and less objective way of saying that fewer trinitrin tablets were needed. Khellin also produces bronchial dilatation, and the report contains an account of its use in bronchial asthma and chronic cor pulmonale.

THERMAL COAGULATION OF SERUM

ABNORMALITIES in the blood proteins of patients with cancer have been described lately by Huggins and his colleagues,⁴ who in this work have made use of thermal coagulation—a procedure which they claim to be simple and reproducible. In 1918 Belak observed the constancy of the coagulation point of human serum, and in 1936 Glass noted elevation of the level in the serum of patients with cancer and also of others. Last year Huggins and Jensen⁵ found that the coagulation of serum albumin could be prevented by halogenated acetates, the most effective of these acetates was the iodine compound, which did not prevent denaturation but eliminated the association of denatured polypeptide chains. It was then learnt that the serum of most patients with cancer, and of some cases of certain other diseases, required less iodoacetate to prevent coagulation by heat. Defects in the coagulative capacity of a serum were measured both by the "iodoacetate index"—that is, by estimating the amount of the inhibitor required—and by the "least

coagulable concentration value," which is arrived at by diluting a sample of serum until it is still just able to form a solid gel on heating. Of the two methods, the second has proved the more satisfactory. To express the values in terms of actual protein concentration, the least coagulable serum percentage is multiplied by the number of grammes of total protein in 100 ml of serum.

In 109 healthy controls the lowest coagulable serum percentage varied from 14 to 21%, while the least coagulable protein concentration varied from 1.06 to 1.38 g per 100 ml. In contrast to these presumed normals 113 consecutive cases of untreated early or moderately advanced malignant disease had concentration values from 1.17 to 2.47 g, and of the whole group, only 17 had values under 1.38 g. In another group comprising 133 cases of diseases other than cancer, 88 fell within the range of normal. Of 91 pregnant women 54 gave a value over 1.38, but in all cases the duration of pregnancy exceeded twelve weeks. Thus, changes in albumin detectable by thermal coagulation are not specific for cancer. Not only are these changes found in other diseases but they are associated with the latter two thirds of pregnancy, and they also arise after severe operations. Huggins and his associates regard serum coagulation as a procedure supplementing the sedimentation rate, with which it has no true correlation. So far as the iodoacetate index is concerned, Huggins, Miller, and Jensen⁶ found it pathologically low in all of 85 consecutively studied patients with cancer which they describe as 'clinically active,' but in only 16 out of 95 cases of non-malignant disease they conclude that the test although not to be regarded as a specific diagnostic measure for cancer, is nevertheless of use. However less satisfactory results are now reported by Gilligan, Rothwell, and Warren.⁷ With this "Huggins" test positive results were recorded in only 72% of 54 cases of cancer, the remainder were all "active," and indeed some had large and inoperable tumours and evidence of metastases. Moreover, high positive values were obtained in 42% of 107 cases of non-malignant diseases, but some of these were chosen because they were febrile and thought to be likely to give positive values. These authors conclude that the iodoacetate index, as related to the serum total protein concentration, while yielding useful information concerning a systemic effect of certain cancers, is not useful for the diagnosis of cancer. However they found that in normal subjects it showed less overlapping with the results obtained in patients with cancer than did the test for the least concentration of heat coagulable protein, and the iodoacetate index as related to the albumin concentration of the serum. Whether these further tests will be welcomed remains to be seen, at present the need is for more precise methods of rapidly estimating protein fractions in small quantities, rather than for tests which are mainly qualitative.

Huggins et al.⁶ also describe a qualitative test for gamma globulin, which consists in mixing 0.05 ml of serum with 0.95 ml of a buffer and heating in boiling water for two minutes. A heavy cloud or the formation of solid particles signifies an abnormally high content of gamma globulin, in health, serum becomes only opalescent or slightly hazy. This test was carried out on serum from 21 cases of multiple myeloma, 7 of the patients had Bence Jones proteinuria but in only 1 of these was the test positive. By contrast, it was positive in 12 out of 14 patients with myeloma who had no demonstrable Bence Jones proteinuria. This test appears, therefore, to be of value in the diagnosis of multiple myelomatosis in which there is hyper gamma globulinaemia without proteinuria.

ROYAL SOCIETY OF MEDICINE

SINCE the start of the late war the number of fellows of the Royal Society of Medicine has doubled, and fellows, members, and associates now total 9714, the growing popularity has not brought growing fortune: in fact the subscription has had to go up to cope with the expanding demands, including the demand for more space. One reason for the increase in members is the society's remarkably comprehensive library service, the council's report for the past year shows that the library now takes over 1400 different journals—a figure which illustrates the growing difficulty of being really well informed. Furthermore, for those within reach of London the sectional meetings give useful demonstrations of the growing points of medicine. During the past year fellows have refused to add to these sections one in haematology, the council is now being approached with a view to forming one dealing with the problem of general practice.

At the annual meeting on July 4, Sir Henry Dukes, O.M., F.R.S., the president, presented the society's gold medal to Prof E. D. Adrian, O.M., F.R.S. "Any physician or surgeon," the President remarked, "who deals today with nervous defects and disorders, finds that his resources of knowledge and of method depend in an ever increasing measure on Adrian's researches, which have already revealed so much concerning the functions, and especially the sensory and perceptive functions, of the peripheral and central nervous systems, and are still progressively disentangling what a less courageous investigator might well have shunned as an intangible and baffling complexity."

Those lately admitted to honorary fellowship (some of whom were present at the meeting) are Prof Wilfrid Penfield, F.R.S. (Toronto), Prof Gösta Forssell (Sweden), Prof Alfred Gigon (Switzerland), Prof B. A. Housar (Argentina), and Prof Abdul Mooro Pasha (Egypt). Officers for the coming years are president, Lord Webb-Johnson, hon. secretaries, Dr A. T. M. Wilson and Mr J. C. Ainsworth Davis, hon. treasurers, Mr L. R. Broster and Dr S. Cochrane Shanks, hon. librarians, Dr T. C. Hunt and Mr H. J. Seddon.

Next year promises to be a busy one for the society, which has undertaken, in response to a request by the authorities, to arrange a series of special meetings in connection with the Festival of Britain. These meetings are to be addressed, according to the council's report "by leaders in all branches of British Medicine, who will be asked to speak on those matters with which their names are internationally associated."

ETHICS AND THE SCIENTIST

SCIENTISTS have evolved an unwritten code of professional ethics. Has the time come to state this code formally? Pigman and Carmichael¹ believe that it has, and they suggest that scientific organisations, and some agency of UNESCO, should examine the application of scientific traditions to the new conditions of research. "A mere statement of principles would be of help. An extensive codification and attempt to discipline or expose gross violations might be desirable."

THE following have been appointed honorary physicians to the King for three years from July 1.

Dr SAMUEL BARRON, medical officer of health Belfast, Dr W. E. CHESMAN, medical adviser to the Treasury, Dr S. W. FISHER, principal medical inspector Mines Department, Ministry of Fuel and Power, Dr ARTHUR MASSEY, chief medical officer, Ministry of National Insurance, Dr R. H. PARRY, medical officer of health, Bristol, and professor of preventive medicine University of Bristol, Dr H. J. RAE, medical officer of health, Aberdeen, and counties of Aberdeen and Kincardine.

Reconstruction

THE OXFORD PLAN

General Practitioner and Hospital

A TALBOT ROGERS

MB Lond

COMMENTING a fortnight ago on the plight of the redundant registrars, *THE LANCET* said

"The tragedy lies not so much in our inability to offer them consultant appointments as in our failure, so far, to provide conditions of general practice which will enable first rate men and women, with a high level of training, to enter it with interest and confidence. A big step towards providing such conditions would be to create or restore numerous hospital appointments to be held by general practitioners

At least one regional board—that of Oxford—has been thinking along similar lines and has now begun consultations with representatives of executive councils and local medical committees in its region to see whether ways can be devised whereby the talents and experience of suitable practitioners can be used to full advantage

This is a very welcome step, for success here could contribute to the solution of several of our most pressing professional problems. It could provide posts where the well trained ex registrar could find a congenial life in general practice, it would enable consultants to unload some of their routine and time-consuming duties and devote a greater proportion of their available time to more specialised tasks. It would tend to close the gulf that is widening between the general practitioner and the hospital, and by so doing it could help to raise again the declining status of the general practitioner

'AREA DEPARTMENT TEAMS'

The memorandum circulated by the Oxford Regional Hospital Board as a basis for discussion aims at 'bringing the general medical practitioner into a more satisfying (to him) relationship with the hospital service by giving him within the hospitals themselves, status and work appropriate to his qualifications and experience,' while, at the same time ensuring that the practitioners do not undertake such tasks as acute general or special surgery "otherwise than as members of area department teams under the supervision of consultants"

This conception of the "area department team," is the key of the Oxford plan. "Under this plan all those working in a particular branch of medicine or surgery in a given area will become members of a team—the area department of medicine, or surgery, or obstetrics, or ophthalmology, as the case may be. Each team or department would include, not only the consultants and senior-hospital medical officers graded in that specialty, but also general practitioners in that area qualified or experienced in the particular specialty and willing to undertake work in it under the general supervision of the specialist staff. The precise method of achieving this objective is for discussion, but it might, for instance, be arranged that those who were willing to do so might be given some position analogous to that of clinical assistant (though given, perhaps, some other title) in the key hospital of the area, combined with an appointment to the staff of a smaller hospital in their own area where they would undertake such work as might be delegated to them by the specialists, who would retain clinical responsibility for the service in the area."

This is a grand conception and by no means an impracticable one. On a smaller scale it is already work-

ing in a few general hospitals, and experience there has shown that such a system can function happily and to the mutual advantage of the consultant, the general practitioner, and the hospital

A PRECEDENT

As a general practitioner, I have myself had the advantage of working in a hospital which has, in recent years, progressed from having only a general practitioner staff, with limited consultant help, to being staffed by regularly attending consultants in almost all specialties, who now take clinical responsibility for all the patients. On the change over, room was found to include in the establishment of the hospital those general practitioners who had the desire, the necessary experience, and the time, to become members of the different consultant teams. Under our arrangement not more than one general practitioner is attached to each consultant, he occupies a position somewhere between the consultant and his house officer (akin to that of a first assistant in a teaching hospital firm), he accepts the duty of attending the hospital whenever his chief is there (whether in the wards, the theatres, or the outpatient clinics), and he attends on other days also, to keep a watch on the progress of the patients and to be available to give advice or assistance to the house officers. In hospitals where the visiting consultant can make no more than one or two visits in the week, and where most house officers are relatively junior, the continued employment of an experienced practitioner, who soon learns the ways and wishes of his chief, provides a most valuable and unchanging unit in the specialist team, it facilitates holiday arrangements, and makes sudden absences through sickness or other unpredictable cause much less disrupting.

So far as my own hospital is concerned the experiment has now proved its worth over four years, and a recent resolution from the hospital staff committee to the management committee said that if it were ever decided that the general practitioner help was to be withdrawn, the present work of the hospital could not be continued without a larger establishment of registrars or of junior consultants. The Oxford plan broadens our experiment, and, by applying it to a group of hospitals in an area, offers still greater opportunities for cooperation between the specialists themselves and between them and their colleagues in general practice. It should allow of greater flexibility and easier adaptation to local needs and to the local availability of suitably experienced general practitioners. Besides the specialties mentioned by Oxford, our experience has shown the usefulness of general practitioners also in the departments of paediatrics, dermatology, orthopaedic and traumatic surgery (particularly for plaster work), physical medicine, and anaesthetics. There is undoubted scope for them likewise in the care of the aged sick.

DIFFICULTIES

But before wide use can be made of practitioners in this way, we shall have to solve many practical problems. Some of these concern the executive councils and the local medical committees as much as, or more than, the regional board, and they demand joint consultation of the kind Oxford proposes.

To begin with, this is a selective scheme, aimed at employing only a proportion of the practitioners—those with special experience—as units in specialist teams. It is not, and can never be, a substitute for the provision of general practitioner beds available for all general practitioners to treat those patients whose need is for nursing care rather than for specialised medical help. Such beds would still be needed even if the Oxford plan were successfully and widely applied.

As to selection, the Oxford memorandum says "where the general practitioner already has hospital attachments, the problem is not only to ensure that he continues to do so, but also to take care of the position when the time arises for the executive council to appoint a successor in his practice". It goes on to insist that the regional board has a duty to ensure that the quality of the staff it employs is adequate to the tasks entrusted to them, and to suggest that there should be joint action in the filling of a practice vacancy which might involve the chosen practitioner's appointment to an area department. This should not be a difficult point on which to obtain agreement, and cooperation, as well with the Medical Practices Committee as with the executive council. The executive council that cares for the quality of service it provides in its area should welcome any opportunity that is offered for obtaining experienced doctors, and by permitting their continued association with hospital work, for keeping their specialised skills from growing rusty.

Nevertheless it will still have a first duty to see that the general medical services provided for the patients on the doctor's list are not hopelessly hurried or scamped because the doctor is choosing to devote an undue proportion of his time to hospital work. The conflicting calls of the two parts of the service have to be met, and it is obvious that a doctor who undertakes to give a regular proportion of his time to the hospital must expect to limit in proportion the number of patients whose care he undertakes. In practice a rough and ready ratio is that for each weekly half-day of hospital service, the practitioner's list needs to be reduced from the permitted maximum by some 500 patients. Some latitude should be given to allow for the help that a practitioner may be receiving from a partner or an assistant, which may well enable him to give more service to the hospital without his practice suffering neglect. The advice of the local medical committee on such points as this would be of great value to the regional board and should always be sought.

Provided his practice commitments allow (not forgetting his maternity engagements if he is doing midwifery), it is desirable that the practitioner should undertake to spend two or three weekly half days at the hospitals in his group. If he gives less time than this, it is doubtful whether he can retain the skill and experience which the regional hospital board can justifiably ask of him. To devote this time will mean for many busy practitioners a drastic limitation of lists, which on balance will be financially disadvantageous to them, even though they are paid for their hospital duties at S.H.M.O. or "10B" rates. There is little doubt that, in spite of this, there would at present be no shortage of applications from experienced established practitioners or well trained would be entrants to general practice, wherever a progressive regional board was willing to carry out a policy of area specialist teams.

FUTURE RECRUITS

As for the future, even the more conservative plans for registrar establishment admit the need for a sharp pruning of their numbers, at some stage—preferably at the end of the middle period—so that an unduly large cadre are not kept in training as senior registrars with little hope of achieving full consultant posts. If this process of reduction becomes the custom, there will always be an appreciable number of men and women seeking to enter general practice after they have completed three or four years of special postgraduate training. The wide fulfilment of the Oxford plan is the only means of creating a pattern of general practice which they can be more than content to enter and sustain.

ECONOMY IN PRESCRIBING

COMMITTEE'S INTERIM REPORT

IN its first interim report, the joint committee for prescribing¹ set up, under the chairmanship of Sir Henry Cohen, by the Central Health Services Council, recommended that practitioners taking part in the National Health Service should be sent a letter urging economy in prescribing. This recommendation was accepted² in its second report,³ which has also been accepted, the committee goes some way towards defining acceptable preparations.

In the National Health Service practitioners are required to order "such drugs and prescribed appliances as are required for the treatment of any patient". When, however, it appears to the Minister that there is *prima facie* evidence that the cost is unreasonably large, he may refer the matter to the local medical committee and if the doctor's explanation to that committee is unsatisfactory, he may have a sum withheld from his remuneration. (In Scotland the institution for investigation rests with the local medical committee.)

The joint committee agreed at the outset that "there should be no absolute restriction on the prescribing by a general practitioner of any drug which in his opinion was necessary for the treatment of his patients". Thus, whatever classification were made, practitioners should not be prevented from going beyond its bounds, though they might have to justify their action to the local medical committee.

A minority of the committee held that any list of drugs that could, or should not, be prescribed would be resented by practitioners and would foster a belief in the minds of the public that some drugs, however essential, could not be obtained under the service. The majority thought, however, that practitioners would welcome guidance from such a list.

The committee, with one dissentient, agreed that it was undesirable that medicinal preparations advertised direct to the public should be prescribable under the service. It also agreed that all drugs and preparations described in the *British Pharmacopoeia*, the *British Pharmaceutical Codex*, and the *National Formulary* (except those classified as foods, toilet preparations, or not drugs for N.H.S. purposes, by the definition of drugs joint subcommittee) should be freely prescribable. These drugs and preparations are referred to as "standard" or "official".

The report divides proprietary preparations into the following six categories:

- 1 New drugs of proved value not yet standard
- 2 Proprietary brands of standard drugs, singly or in combination
- 3 Standard preparations, and new remedies of proved value, in elegant form or vehicle
- 4 Qualitative and/or quantitative modifications in the composition or combination of standard preparations, or new remedies of proved value, which are not accepted as therapeutically superior to preparations included either alone or in combination in the B.P., B.P.C., or N.F.
- 5 Preparations not in the B.P., B.P.C. or N.F. which in the committee's view have not been proved of therapeutic value
- 6 Preparations which are a combination of 4 and 5

It is recommended that proprietary preparations in category 1 should be freely prescribable, and that preparations in categories 2-4 should be prescribable subject to (a) their not being designated as foods, toilet preparations, or not drugs for N.H.S. purposes by the definition of drugs joint subcommittee (b) their not being

advertised direct to the public, and (c) satisfactory arrangements for price being made between the health departments and manufacturers. The report concludes—expressing the committee's willingness to classify individual proprietary preparations according to these categories—a task which is expected to take some time. A copy of the report is being sent to all practitioners, and in a covering letter, Sir John Charles, chief medical officer of the Ministry of Health, points out that "rather more than 30% of the cost of medicines supplied to public students is for proprietary preparations." There are, he says, some proprietary preparations for which there are standard equivalents and which are more expensive than the standard preparations. And he asks that "in many exceptional cases where there is an overriding medical consideration, doctors will seriously consider before ordering one of these proprietary preparations whether the alternative standard drug could not be ordered without detriment to the patient's condition. It will be appreciated that in many cases preparations in this group are advertised direct to the public."

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a dinner on June 27, to celebrate the 150th anniversary of the college's first Royal charter, the Duke of Gloucester, an honorary fellow, recalled that the college was incorporated in 1800 by charter of King George III. Queen Victoria had approved the institution of honorary fellowship to mark the centenary, and exactly fifty years ago—on June 27, 1900—King Edward VII became the first honorary fellow. In this year's anniversary celebrations the first event—on March 20—had been the admission of the Queen to honorary fellowship.

Sir Cecil Wakeley, the president, replying to the toast of The College, proposed by Mr S. C. Roberts, vice-chancellor of the University of Cambridge, traced the history of the college in the past century and a half in the first hundred years it had progressed steadily as a licensing body, with the institution of the fellowship in 1843, the licence in dental surgery in 1859 and the Conjoint Board in 1884 as the outstanding events. In 1909 the council agreed to admit women to the examinations of the college—a decision taken with the support of the fellows but contrary to the majority view of the members. The appointment, in 1905, of Sir Arthur Keith as conservator of the museum ushered in an era of greatly increased scientific activity. During the presidency of Lord Moynihan (1926-32) the college adopted a wider outlook. Primary fellowship examina-

tions were for the first time conducted overseas—in Canada in 1929 in Australia in 1931. In 1941 the building suffered severe damage by bombing, but within two months Lord Webb Johnson was elected to the presidency, and during his eight years of office the college, "still maimed, mutilated, and preoccupied with licking its sores, yet displayed a vigour incomparably greater than at any other period of its existence." In the present scheme for reconstruction and expansion—including the Nuffield College of Surgical Sciences—there was still no determined plan for the use of college property on the west side. "I wonder whether even now it is not too late to hope that our sister colleges may yet be our neighbours?"

Sir John Anderson replied for The Guests to a toast proposed by Lord Webb Johnson, who paid tribute to those who down the years had aided the college. Lord Webb Johnson expressed satisfaction at finding himself between the presidents of the two senior English Royal Colleges—with, as he put it, "Brain on the one hand and brawn on the other." Many, he concluded, had felt that the Royal Colleges of England, based on London, should coöperate more closely with the University of London, and it seemed that closer coöperation was near.

At the dinner Sir Henry Newland for the Royal Australasian College of Surgeons, presented a silver tankard, and Dr Louis Bazy, for the Académie de Chirurgie, a medal, which were received on behalf of the college by the Duke of Gloucester.

Before the dinner the president, accompanied by the council, received congratulatory addresses from the presidents, deans, or other representatives of the following bodies:

Barbers Company (founded in 1308), St Andrews University (1411), Royal College of Surgeons of Edinburgh (1505), Royal College of Physicians of London (1518), University of Dublin (1591), Royal Faculty of Physicians and Surgeons of Glasgow (1599), Society of Apothecaries (1617), Royal Society (1660), Royal College of Physicians of Ireland (1667), Royal College of Physicians of Edinburgh (1681), London University (1836), Académie de Chirurgie (1843), Manchester University (1851), General Medical Council (1858), Royal College of Surgeons in Ireland (1874), University of Wales (1893), Birmingham University (1900), Leeds University (1903-04), Sheffield University (1905), Bristol University (1909), Queen's University, Belfast (1909), American College of Surgeons (1913), Royal Australasian College of Surgeons (1927), Royal College of Physicians and Surgeons of Canada (1929), and the Royal College of Obstetricians and Gynaecologists (1929); and also the British Postgraduate Medical Federation, and the medical schools of Guy's Hospital, King's College Hospital, St Mary's Hospital, and University College Hospital.

Sir Henry Newland presenting the Australian college's address

Parliament

The Medical Bill in the Commons

IN moving the second reading of this Bill in the House of Commons on June 27, Mr ANEURIN BEVAN said that the Bill came from another place where a number of amendments had been accepted.¹ He believed that there was general agreement with the main purposes of the measure, which did not set out to undertake a complete revision of the medical Acts. The first purpose of the Bill was to improve the standard of medical education. It provided that the student after passing his final examinations should be put on a provisional register until he had completed a period of intern service. Mr Bevan pointed out that the General Medical Council still exercised some jurisdiction in relation to the Republic of Ireland, and it had been necessary to ensure that the new arrangements were acceptable to the government of the republic. He was glad to say that complete agreement had been reached. New South Wales and the Union of South Africa already had a compulsory intern service, but other countries with which we had reciprocal relations were not yet ready, and time for consultation and adjustment would have to be given before the new arrangements were enforced.

The Bill also provided, Mr Bevan continued, for the visitation of the medical schools. Power to give directions to the G.M.C. in this connection had been given to the Privy Council. This had been done because the Government were anxious to ensure that any influence over the academic side of medicine should be exercised by authorities like the Privy Council and the General Medical Council, and not directly by the Government. This provision, he added, required no long advance administrative arrangements and should come into operation almost immediately.

Mr Bevan then briefly outlined how the Bill altered the constitution of the G.M.C. and improved the disciplinary machinery, giving the council power to take evidence on oath and to subpoena witnesses. Another important provision was the right given to a doctor whose name had been erased from the Register to appeal to the judicial committee of the Privy Council. He commended the Bill to the House and hoped members would give it a smooth and speedy passage.

Lieut.-Colonel WALTER ELLIOT thought that the Bill was one to which the House would certainly give a ready assent. As the Minister had pointed out, its main purpose was the improvement of medical education. Here the important step had been taken of recommending that an additional year should be added to the medical curriculum. There was a danger, Colonel Elliot admitted, that the curriculum might be unduly prolonged. He yielded to no-one in his admiration of the training which our hospitals gave to young graduates in their housemanship. The great hospitals had the power to buoy up a man to an extent he never realised until he tried to tackle the problems on his own. Housemen's posts would be difficult to get, and appropriate responsibility would be a difficult thing to devolve upon them. The extra year would need to be looked at with great care to make sure that a sense of responsibility was really developed and that it was not merely used as a further occasion for learning.

A DISSENTING VOICE

Dr H. B. MORGAN said he must oppose the Bill. Three functions attached to the G.M.C. First came the supervision of the *British Pharmacopœia*, which had been very well done. But the second function—medical education—was very bad. There should be in this country, Dr Morgan declared, a one portal system of entering the medical profession—one fixed standard for all students. Then, if a man wanted to specialise he could do so by postgraduate courses. He thought that in laying down a medical curriculum they should take note of the organisations, such as the colleges, which made no provision for training and were purely examining bodies, sometimes claiming revenue from those they deliberately flouted. The Trades Union Congress, he continued,

was very keen on medical education and wanted industrial medicine taught in the medical schools. The T.U.C. had asked the G.M.C. to include this subject in the ordinary curriculum. What had the medical schools done? Simply nothing. In only three—Glasgow, Manchester, and Durham (Newcastle upon Tyne)—were there professors in that subject. This Bill looked a innocent little measure, but at the back of it there were great powers against the democratic administration of medicine. Suppose a man did not want to go into consulting, or even general, practice, was he still to be forced to attend for another year before registration? Suppose he wanted to go into medical research, must he waste another year in a subject in which he was not interested? Dr Morgan added he would like to see the Bill reconsidered.

Dr CHARLES HILL pointed out that Dr Morgan ignored the fact that the rôle of the G.M.C. was to secure a minimum standard, and licensing bodies were left to apply a standard in excess of that minimum if they chose. He sympathised with Dr Morgan's enthusiasm for industrial medicine, but he suggested that the part of the Bill which strengthened the power of the G.M.C. in visiting medical schools would enable the Council to exercise a stronger influence over them. Dr Hill trusted that the proposed intern period would not merely add a year to the curriculum. He hoped rather that this proposal would mean that towards the end of his career, when examinations were out of the way, the student was enabled to assume a post of some responsibility under supervision. He hoped that the new posts would be designed in relation to the functions they had to fulfil. It had been suggested that a good way of spending this last year would be for provisionally registered medical practitioners attached to a hospital to be allotted patients on their coming to hospital for treatment, and to follow those persons throughout the whole of their treatment back to their homes with a measure of responsibility for that treatment. The full fruits of this important new development would only be secured if that year was related to a revised medical curriculum and special posts and the right kind of responsibility were created for the purpose. He was glad that discipline was to be a matter not for the council as a whole but for a committee specially established for the purpose. That would lead the council to think more and more about medical education. But he did not like the arrangement under which the penal cases committee could decide whether there existed sufficient evidence to justify the investigation of a case. No person involved in the original assessment of cases ought to be a member of the disciplinary committee.

Dr A. D. D. BROUGHTON pointed out that the benefits to be derived from a period of postgraduate work under supervision in hospital were no recent discovery. Many had taken advantage of it in the past, more were doing it today. But some doctors had been denied that valuable experience by lack of funds. This Bill might serve as a reminder that a course of training in medicine was a very long one, and that might lead in turn to a revision of the medical curriculum to allow the schoolboy to learn more about the arts before embarking upon years of intensive scientific study.

SOME DIFFICULTIES

Surgeon Lieut.-Commander REGINALD BENNETT agreed that a good deal of lopping was possible in the medical curriculum. He had some misgiving that adultery should be the one type of civil case in which the G.M.C. disciplinary committee should not have power to call further evidence before pronouncing judgment.

Mr SOMERVILLE HASTINGS welcomed the Bill because it made the education of British doctors, already the most practical in the world, even more practical. The trouble today was that there was too sharp a division between the time when as medical student the young doctor had very few responsibilities and never had to make decisions, and the time when he suddenly became qualified and found that the life and death of his patient depended upon his diagnosis, and sometimes even upon his treatment. This Bill was good because it made the division between irresponsibility and responsibility gradual. He accepted completely the general principles

the Bill, but he felt that thought should be given to a question how they could be carried out. He could see that there were enough suitable appointments for interns to go round. There were some hospitals where the young doctor would learn mainly what not to do. Again in teaching hospitals the physician or surgeon had often drawn to him cases of a special type, and those he treated usually by operations. Such cases might be relatively rare, and though of great importance, a young doctor who went into practice might not be likely to meet many of them. Therefore, while such appointments would be valuable for the training of specialists, he did not think that they would be of much value to the general practitioner. Again there were difficulties in deciding whether a young doctor's work as satisfactory and there were difficulties in the case of a physically handicapped person. What about the man who had lost the whole or part of his hand? He certainly could not be an efficient house surgeon or indeed take an appointment as an obstetrician. Yet the Bill said that such a man had to serve part of his time in one of these capacities. Mr Hastings was glad to see service in a health centre would do just as well as service in a hospital, but at present the health centres did not exist. Moreover, while he agreed that to help an efficient doctor in a health centre would be most valuable training for a general practitioner, he felt that service in a special department in a health centre should only count as training for a specialist.

He was disappointed about the constitution of the G.M.C. It had been generally recognised that it was safe to leave the conduct of most professions mainly in the hands of their members. But here they had a G.M.C., which was to consist of 47 members, of whom only 11 were to be elected by the profession. Were doctors less responsible than nurses? The Bill greatly improved the disciplinary procedure, but Mr Hastings would have liked to see some lesser penalty than being struck off the Register.

Dr BARNETT STROSS thought the Bill a modest and unassuming measure, and there was nothing particularly handicapping in life about modesty. But it had certain disturbing aspects. Despite the suggestion that there would be a year's extra work before full qualification, the word "satisfactory" was used and they would want to know what it meant. They would also like to know whether, if the student was injured during his training, or if he fell ill, possibly with infantile paralysis, he was to be denied any opportunity of further work or of service with approved institutions. They would want to know how long the student might have to wait for an approved post.

Mr HUGH Linstead paid tribute to the work which the G.M.C. had done over years with an extremely clumsy machine which yet seemed to function with efficiency and justice. The G.M.C. had been originally quite an appropriate body to supervise the production of the *British Pharmacopœia*, but with the passage of years they had handed the duty over to the Pharmacopœia Commission composed of one or two doctors, but mainly of chemists or pharmacists. He hoped that the House would be assured that they were not crystallising by the chance reference in this Bill the existing method of producing the *Pharmacopœia*, which was by no means considered suitable in all quarters.

Miss MARGARET HERBISON, joint under secretary of State for Scotland, replying to the debate, said there had been much criticism of the overloading of the curriculum in the medical schools and the debate might bear some fruit in that matter. She thought that Dr Morgan was a little less than fair when he suggested that in our medical schools and universities almost nothing was done in industrial medicine. The Government did not say that they were satisfied that what was being done was sufficient, but they were absolutely satisfied that the correct way of getting industrial medicine, or any other subject, into the curriculum was not by vesting power of direction in the G.M.C. This Bill provided that visitors not merely examined an examination but what really was being taught in the medical schools. In this way it was hoped that the G.M.C. would be able by persuasion, not by force, to make those

changes in the curriculum which public opinion thought necessary.

Replying to some of the points raised about the intern post, Miss Herbison said they would of course carry a salary. A doctor on the provisional register would be able to sign a death certificate. The suggestion that the year should be spent in general practice as a trainee assistant was contrary to the Goodenough recommendations, the views expressed by the G.M.C., and the practice in our Empire countries. It was felt that the best experience could be got in hospitals and that it would be difficult to provide adequate supervision in general practice. The Government suggested it would be better to see how the scheme worked in hospitals before any further extension was made for experience in general practice. They were still leaving the intern period at 12 months but they could not at this stage say how soon they could make the figure work. There might be difficulty in providing enough posts in Scotland, where a third of all our doctors were trained, but perhaps England would provide the beds for some of these.

The Bill was read a second time.

Midwives (Amendment) Bill

In the House of Commons on June 28 this Bill, which has already passed through the House of Lords, was considered on report. Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, moved an amendment making it quite clear that the midwife would have the full right to wear the new national uniform if she so desired, even though there might be an agreement with the local authority in regard to some locally designed uniform. He said that this was a small matter and was limited by the Government amendment to domiciliary midwives. The amendment was agreed to. The Bill was read the third time and passed.

QUESTION TIME

Pay of Specialists in Pensions Ministry's Hospitals

Sir IAN FRASER asked the Minister of Pensions when it was proposed to apply the scales of remuneration authorised by the Minister of Health to specialists employed in Ministry of Pensions hospitals—Mr H. A. MARQUAND replied. The question of the remuneration of specialists in the Ministry of Pensions hospitals is being remitted to an independent committee set up in accordance with the recommendations of the Chorley report, which will review the pay and grading of all medical officers in the Civil Service. Sir IAN FRASER. In considering this matter will the Minister bear in mind that many of these specialists who are doing comparable work, are now being paid less than half what is paid to similar grades in the National Health Service, and that it is so bad that the *British Medical Journal* refuses to advertise for these grades?—Mr MARQUAND. I am well aware of the situation, that will all be in front of this committee.

Lieut. Colonel WALTER ELLIOT. Can the Minister say when he expects the committee to report? There is a serious drain on the service owing to the difference in the conditions between the two ministries—Mr MARQUAND. I am not aware of any serious drain. The committee is just commencing its deliberations, and it would really be for the Financial Secretary to the Treasury to answer questions about the date of the report.

Smallpox Textbook

Mr S. P. Viant asked the Minister of Health if, in view of the serious consequences which attended the accidental introduction of wrongly diagnosed cases of smallpox into general hospitals, he would consider issuing a textbook on the diagnosis of smallpox for the use of hospital doctors and also for medical students who were studying for the diploma of public health—Mr A. BEVAN replied. I do not think it is within my functions to publish medical textbooks, but I will have the objective underlying the suggestion considered.

Allowances for Invalid Children

Sir RICHARD ACLAND asked the Minister of National Insurance what provision was made for children, or for parents of children, who were invalids from an early age and who ceased to be eligible for children's allowances on reaching the age of 15, and whether she would give an undertaking that the position of such children would be

considered when the present insurance schemes came up for general review—Dr EDITH SUMMERSKILL replied. If through inability to attend school an invalid child has ceased to qualify for family allowances at age 15, his father, when not fully employed, may claim national assistance in respect of him. At 16 the child may apply for national assistance in his own right. The position of these children will be considered further in any future review of the schemes.

Air-mail Envelopes and Eyestrain

Replying to a question, Mr NESS EDWARDS stated that one of the reasons for prohibiting the use of air mail envelopes with coloured borders was that the post office had been medically advised that the use of envelopes with multicoloured borders was undesirable as they are a potential source of eyestrain.

Hospital Beds for Tuberculosis Patients

Brigadier F. MEDLICOTT asked the Minister of Health if, in view of the fact that 11,000 people suffering from tuberculosis were awaiting hospital beds, he would give favourable consideration to the suggestion that a minimum of 10% of the beds in general hospitals should be set aside for tuberculosis cases—Mr BEVAN replied. Yes, I am doing so. But there can clearly be no set rule about it.

Cost Allowance on Drugs

Colonel L. ROPNER asked the Minister of Health why, without effective consultation with their central committee or awaiting the findings of the Whitley Committee which was inquiring into this matter, he had imposed upon chemist contractors, under the National Health scheme, a cut from 33% to 16% in the cost allowance on drugs supplied by them under prescription—Mr BEVAN replied. I am determined that all unnecessary expenditure on the National Health Service should be eliminated, and after consultation with the chemists' representatives in accordance with the regulations I was satisfied that there were grounds for an immediate provisional reduction in this allowance. Negotiations are proceeding, however, and I have undertaken to accept whatever final percentage may be agreed by the Whitley Council or awarded by an arbitrator.

Mileage for Rural Doctors

Dr A. D. D. BROUGHTON asked the Minister of Health whether he would increase the mileage allowance for general medical practitioners in rural areas to compensate for the rise in the cost of petrol—Mr BEVAN replied. I am always ready to discuss with the profession any ideas for the better distribution of the total moneys available for general practitioners. But I could not regard the imposition of a new tax as justifying any addition to the total amount.

Dr BROUGHTON. Is the Minister aware that much of the help which he gave to the rural practitioner by increasing the mileage allowance a short time ago has now been counteracted by the rise in the cost of petrol?—Mr BEVAN. If every time a new tax was imposed reliefs were given to meet it there would be no revenue from new taxation.

Mr A. E. BALDWIN. Could not the Minister give more sympathetic consideration to this matter, which is causing hardship to doctors in scattered rural areas? May not the result be greater difficulty in getting doctors for scattered areas?—Mr BEVAN. I have not yet observed that the members of the medical profession are deficient in organisations to put forward schemes on their behalf.

'Agene' Process

Dr BARNETT STROSS asked the Minister of Food how soon all flour treated by some form of improver would be so treated that the agene process could be forbidden, and whether he would estimate the cost in dollars for machinery and chlorine dioxide, which must be imported from the United States of America—Mr MAURICE WEBB replied. It will take about two years to complete this change, and it will probably cost about 337,000 United States dollars.

Dr STROSS. Is the Minister aware that there is a considerable body of medical opinion that believes that peptic ulceration is aggravated by the agene process and that this has been responsible for the increase of duodenal and gastric ulcers within recent years? Will he give the House an assurance that as soon as possible we shall be free from this somewhat poisonous improver?—Mr WEBB. Two years is the period.

Public Health

Infectious Tuberculosis in London

At a meeting last Tuesday, the London County Council agreed that the Ministry of Health should be approached with a view to clarifying the responsibility, as between regional hospital boards and local health authorities, for the care of tuberculous patients who can receive no further benefit from sanatorium treatment but who have no homes or whose home conditions are unsuitable.

The council's health committee estimates that in common lodging-houses in London there are some 17 chronically infective people with little or no working capacity. Before the start of the National Health Service the council accommodated the chronically infective in small voluntary sanatoria.

"Since 5th July, 1948, however," the health committee reports, "difficulty has been experienced in finding accommodation for them, as owing to the pressure on hospital beds for acute cases the Metropolitan Regional Hospital Boards have been unable to provide accommodation. I take the view that these cases are not their responsibility."

It was contemplated by the council that, under section 28 of the National Health Service Act, such sanatoria would ultimately be established in various parts of the county, where possible in conjunction with special workshops to be provided by the Disabled Persons Employment Corporation. The council submitted a proposal for the demolition of St Peter's Hospital, Stepney (which was not transferred under the Act) and the erection of a night sanatorium and industrial workshops, but the Minister of Health, though approving the proposal in principle, rejected it because of the cost.

As regards hostels, the committee is in doubt whether the responsibility lies properly with the council, as a local health authority, or with the regional boards.

"A hospital authority has responsibilities in many fields extending beyond treatment and it can be held that the provision of institutional accommodation should not be limited to persons for whom treatment is a primary consideration. Though medical skill may be unable to do much or anything for the ambulant chronic infective tuberculous person, he may at any time require urgent admission to hospital and if hostels of this type were controlled by the Regional Hospital Boards such urgent admissions could be arranged more easily than if two separate administrative bodies were concerned. Moreover the staffing of hostels would be difficult and would present an easier task to an authority having a large institutional staff than to one controlling only a few institutions of like and, so far as staff is concerned, unattractive kind."

"We are satisfied," the committee concludes, "that the urgent nature of the problem requires an early decision so that whatever the decision is urgent action can be taken."

Smallpox on a Vessel

A Goanese seaman was landed from s.s. *Strathmore* at Aden on June 19, believed to be suffering from chickenpox. The diagnosis was later confirmed as modified smallpox. Passengers and crew were vaccinated during the voyage. The vessel arrived in the Port of London on the morning of July 2. There was no case of sickness on board on arrival. Some 1200 passengers and crew disembarked and were placed under surveillance in the areas to which they proceeded, until July 5. Practitioners are advised to consider a diagnosis of smallpox if a person who travelled on this vessel falls sick. Revaccination may cause extreme modification of the clinical illness and of the exanthem.

Poliomyelitis

The numbers of notifications of poliomyelitis in England and Wales during the week ended June were paralytic cases 104 (77), non paralytic cases (16). Figures for the previous week are shown in parentheses. Although this is a substantial increase, the high prevalence still seems to be chiefly confined to a relatively limited area of the Midlands. There were 45 notifications in Warwickshire, of which 11 were in Birmingham; 9 in Staffordshire and 14 in Worcestershire. The epidemiological picture differs from that in the corresponding weeks of 1947 and 1949.

In England Now

-Running Commentary by Peripatetic Correspondents

THE other morning I woke early, full of joy, saying to self "ah, it's my birthday today." Then Henrik, elder son, came in and asked for sixpence for something at school. I asked him if he knew what day it was, he said it was Tuesday. After a while my wife woke up and very kindly congratulated me, and I thought "now the celebrations begin." The front-door rang, I got up in a hurry to take in all the parcels. It was the postman all right. He left one letter—a card from a drug firm. My wife had now fallen asleep again, Henrik had started to school with his pence, and Anne, though rising four, never seemed to have heard of her father's birthday. I was thinking sadly about inconstant friends when I heard our maid coming about in the dining room. I went in with a smile, thinking that this simple, but honest, soul would say "Oh, sir, I have fried two eggs for you this morning." Her eyes were closed with oedema, and she was crying, not a word of congratulation. I asked if she had dropped something and she said "No no no", and after many desperate attempts sobbed out that she was expecting a baby in September. Despite this catastrophe I got my breakfast and went to the hospital where I met the matron and thought of the nice box of chocolates I had given her for her birthday. She said she was glad to see me, but it was only because the day before I had done a total colectomy for a patient with ceratotic colitis and he was very poorly and no-one knew what to do. When I got home to lunch, more miserable than ever, I asked my wife if she didn't think queer that I hadn't had a word of congratulation from anyone. She asked if I'd written to James, or John, or Marcus on their birthdays, and I suddenly realised I hadn't the faintest idea when their birthdays were. That helped me a lot. I got hold of the telephone, and called Nils and some others. We had a very good party here everyone enjoyed themselves thoroughly and nobody thought about my birthday. My friends may, however, care to know that this all happened on May 30.

One of my colleagues recently went up on a Short List job. You would have thought he was just the man for the job. He had experience and all the right qualifications. He went up wearing an inoffensive *sab fusc* cravat, a clean handkerchief, and a Hawks tie (borrowed on the occasion), and he had been properly coached for the Ritual. He entered on all fours, caressed the left foot of each member of the board in correct order of precedence, and withdrew from the Presence backwards. He gave (to my mind) perfectly adequate answers to the Three Riddles, and his manner throughout was conciliatory and polite. And yet he was chucked out. Why? Simply because he had forgotten to remove his hat.

Many people fall down over the Three Riddles. The Riddles vary slightly in different localities, but a working knowledge of ten or a dozen "spot" riddles (obtainable from any reputable coach) will cover most contingencies. You may wonder whether there are right (and therefore wrong) answers to these riddles, or whether they are asked blindly just to see what they bring forth, like those nightful questions the Phosphorescent Unmentionables used to fire off at you at Wosbees. There are, of course, so universally correct answers. An answer which is applauded in the Metropolitan Area (and how those boys can whistle and stamp!) may well evoke raspberries in the North. Take, for example, the classic "What would you do if you were granted six months' study leave?" Any decent Londoner would unhesitatingly reply, "Go to the U.S.A. and have some memorable meals." In the Midlands this would merely invite the reply come back, "What's wrong with Blackpool?" Local feeling must be studied and allowed for. In some localities, "Go and work in a lab and bring myself up to date with pathology," is not only swallowed but found palatable.

The question, "What makes you think you are the most suitable man for this appointment?" is a stinker. Don't touch it. Pretend you didn't hear it or change the

conversation, unless you are lucky enough to possess a broad Scots accent and can deliver yourself of some pawky whimsy, like "Och aye. It's like Keith Prowse, ye ken. Ye want the finest doctors. We hahve them." This cannot be rendered satisfactorily in B B C, Oxford, or Cockney.

Another really tricky one is, "What experience have you of filling up forms?" What can one say? "Twenty-five years?" or "So much that I can do them in my sleep?" A friend of mine, a very fine amateur actor, gave a masterly answer. "Well as a matter of fact," he confessed smiling at his finger-nails, "that happens to be rather a speciality of mine. In the first place I never do them during working hours. I always take them home and my wife helps me with them. On Sundays we often take them out in the car and picnic in the woods with them." He clotted it because on his application form he had admitted to being single (although under both headings "Religion" and "political leanings" he had inserted "Mormonism"). Above all things be consistent.

Should the interrogation be unilateral? I think not, and it was welcome news to me that one group of candidates, tired of waiting nearly an hour for the board to assemble, sent out for an extra kitchen chair, and called in those members of the board who were available one by one and subjected them to a stringent interview in the waiting-room. One candidate, whose father was a successful author and dramatist who annually supplied the Exchequer with £15,000, was inclined to cavil at the board's expenses. Another, whose openly avowed ideas of life included things other than 60 working hours a week, inquired about the sporting and cultural amenities of the neighbourhood, and would you believe it, the chairman himself had never heard of Sibelius and didn't even know if there were any good kindergarten schools nearby! All agreed that two of the board were disgracefully in need of a haircut, and further that they wouldn't touch the job with a barge pole. (They all had a date later in the week at a short-list party in a populous South Coast resort, all, that is, except a displaced person who had dozed throughout the proceedings, and got the job. This situation can only arise when it is a buyer's market.)

Statistics can be made to show that every minute of the working day nearly five short-listed doctors are travelling by train at public expense towards selection boards. If you divide by sixty, and multiply by say forty miles an hour and a penny-three-farthings a mile, you get a fantastic figure. Repeat the calculation as often as you like and you'll get similar answers. I would suggest that great saving of both time and money could be effected if short-list conventions were abolished and superseded by a good honest-to-God lottery system, one ticket per candidate and not transferable. All lotteries would be run from one central office by one part-time clerk with a part-time roulette board. Doubtless during the day-time the one from the M R C statistical department could be borrowed or hired.

My hours spent in studying the seed merchants' catalogues in the winter were not wholly wasted, even though I never quite succeed in growing the exquisite blooms and full luscious fruit and vegetables of the illustrations. For I jotted down in my diary a lot of names that are proving useful in discussing pathology with my "popular-science" patients. As I hoped, *schizanthus* and *eschscholtzia* have been a great success in psychiatric interviews. *Streptocarpus* sounded just the sort of new bacterium which would be the cause of Mr Smith's persistent catarrh, and nobody has ventured to question my diagnosis of that rash of young Brown's as *Fulgens multipetala*.

Then this evening, as bedtime approached, I suddenly remembered that I have to attend the local medical society dinner tomorrow night. I recalled with horror the adverse comments last year when I was unexpectedly called on to say the Latin grace and mumbled far too audibly "*Latissimus dorsi pectoralis subclavian, flexor accessorius et extensor carpi pollicis*." But this year all should be well, for I shall say "*Nigella raphanus sativus calendula criniflorum tigrinum splendens et glivssum amaranthus polyanthus lathymus latifolius*."

Letters to the Editor

THE REGISTRAR'S FUTURE

SIR,—It seems to be generally agreed that an alteration in the ratio between registrars and consultants is essential, to give those in training a hope of fulfilling their ambition. But *why* should this be achieved by reducing the number of registrar (and senior registrar) appointments only, without increasing the number of consultancies, as implied in the Scottish survey and your leading article? You say (June 24) "More consultants might be appointed, but the consultant establishments have only lately been fixed, and any substantial increase at this juncture of the nation's (and the service's) affairs is likely to be resisted." If consultant establishments have been fixed, the number of beds and amount of work for which one consultant is expected to be responsible have not been defined. In the former local authority hospitals particularly, owing to the shortage of consultants on the establishment, much work normally regarded as the responsibility of a consultant has devolved on senior registrars and registrars.

The "resistance" to appointing more consultants is presumably on economic grounds. If this is so, the whole question of remuneration in the N.H.S. which has produced such anomalies and dissatisfaction should be reviewed. On the "appointed day," while general practitioners suffered, substantial increases were made in the salaries of consultants, registrars, and house officers. Although this increase was welcome, it was evidently based on miscalculation, and registrars at any rate might have preferred to live at their former standard if this meant more prospect of promotion, and a permanent job. The salaries of consultants under the N.H.S. compare favourably with those of other professions and of others inside the medical profession, and I suggest that no hardship would result if the commencing salary of younger consultants at any rate was lowered.

The Scottish survey suggests as a solution of the problem of surplus registrars "their attachment to hospital departments after they are in general practice." From the frying pan into the fire! The more irksome duties which fall to the lot of the registrar he must for ever bear, without hope of relief after faithfully serving his term, or the satisfaction of being able to concentrate on the more difficult and interesting cases which come to the head of the department. He will become a permanent "assistant without view"—a position as unjustifiable for a specialist as a general practitioner. The Registrars' Group by a majority voted against the idea of "general practitioner consultants." This suggestion is the line of least resistance and would not in the end satisfy the hospitals, the general practitioners, or the registrars themselves.

SENIOR REGISTRAR

A C T H IN RHEUMATOID ARTHRITIS

SIR,—Dr Dresner and his colleagues, in their article of June 24, report that "administration of adrenaline in oil 20 mg daily for 14 days produced no subjective clinical improvement in a case of rheumatoid arthritis. The eosinophils fell to 50% of the resting value during the first 24 hours but thereafter rose to normal resting value." They further remark "Adrenocortical stimulation by adrenaline was less marked than stimulation by A C T H."

There is evidence that *intravenous* adrenaline in effective doses is a very potent stimulator for the adrenal cortex.¹ It is generally taught that in man *intravenous* adrenaline causes ventricular fibrillation and death. If dilute solutions are given slowly however, the case is different. In 1927 I had to treat some 350 cases of Asiatic cholera, under emergency conditions, with a death rate of 50%. I found that *intravenous* adrenaline—six drops of

1 1000 adrenaline hydrochloride in one pint of Ringer's hypertonic saline—had a very improving effect on the in the dreaded "collapse" or "algid" phase of the disease. I mention this experience to show that *intravenous* adrenaline, if used carefully, is not necessarily lethal, but might be beneficial in carefully selected cases. Further evidence of the innocuousness of, and benefit from, *intravenous* adrenaline has been provided by Marcus and Gray.²

It may be that the stimulation of the adrenals must be qualitative rather than quantitative, but this difference is not borne out by the findings of Greene.³ I think the effect of adrenaline by the *intravenous* route is more potent and peculiar than when this drug is given orally, subcutaneously, or even intramuscularly.

A NEW SOCIETY

SIR,—It was nice to see your annotation (June 24) on the formation of the Society for the Study of Fertility, but I should like to make two comments.

1 My remark about the zoological interests of the officers followed a critical discussion as to whether the scope of the society should be restricted to human fertility, and included a reference to the fact that the society proposed to take unto itself an animal chairman—myself. The isolated and abbreviated allusion to this matter in your article may give a wrong impression.

2 My paper on freezing of spermatozoa hinged on the fact that, in our experience and by present methods, mammalian spermatozoa, other than those of man, cannot be revived after rapid freezing at -79°C , but that those of some species at least can be revived after slow freezing. Your report of my paper is, therefore, quite inaccurate.

THE MISSION TO LEPERS

SIR,—The Mission to Lepers was founded in 1843 as an international and interdenominational society, in order to enable Protestant missions to undertake work for those suffering from leprosy—and its social consequences—by giving financial support and general guidance. Since then it has grown into a great society with extensive work in many lands.

In the past it has not been the policy of the mission to send out its own doctors and nurses. This was not necessary so long as the cooperating societies were able to provide the personnel. But today they are unable to do so in sufficient numbers, and this just at the time when the prospects of curing leprosy have been brought nearer by the introduction of sulphone treatment. This has led the council of the mission to decide that the time has come to send out itself a certain number of doctors, nurses, and other medical workers.

There are vacancies at present in India and China for a few men doctors and women nurses. Those who may consider offering themselves should be young, and wholly sympathetic to Christian missions. They should be prepared themselves to serve as medical missionaries and to cooperate wholeheartedly with missions and Churches in the countries to which they go. The field of work offers no financial prizes—ordinary medical missionary allowances will be given—but the work does afford a fine field for Christian doctors eager to give themselves to a difficult task at a time of great opportunity.

Those who wish to apply should be under thirty years of age, and they should send along with details of qualifications and experience, references from those who know their character and capabilities.

though these factors may not be wholly absent Human frailties of this kind we shall always have, but what is now implied is worse than this, it is an error of thinking and method, a true quackery now to be introduced into medicine. In the last resort, such a censorship of hospital research work as is now adumbrated must be the responsibility of a single individual who will have to decide which research project is to be encouraged and which banned. However catholic his knowledge of the vast and variegated field of medical research, no one man can exercise this function rationally or equitably, and he must in undertaking it, become an administrative medical quack.

Moreover, the whole notion betrays an abysmal ignorance of the nature of clinical research. The spirit bloweth where it listeth, and no one can foretell of any research project, within wide limits, what possibilities of fruit it holds. Equally it cannot be foreseen what light a single piece of research may throw upon another and an independent one which covers the same field. We should not say to Goethe "there is no need for you to write a drama about Faust, for a very excellent one has already been written by Marlowe, and we really can't allow you to spend your time and our money this way, for after all, you are a State salaried official." Yet, *mutatis mutandis*, something as absurd and as intolerable as this is what is now proposed.

That a single central authority or person should be imposed upon us to decide which infant idea is to be strangled at birth and which conceded nourishment is a development which will take no wise spectator of what is happening to medicine by surprise, but even the most guileless of us must view it with grave disquiet.

F M R WALSH

GENERAL ANÆSTHESIA FOR BRONCHOGRAPHY IN CHILDREN

SIR,—I have read with interest, in your issue of June 10, the technique employed by Dr Way and Mr James for anæsthetising children for bronchography, but I agree with Dr Wright (June 24) that the dosages of thiopentone mentioned may be dangerously large. I have known 0.5 g of 5% thiopentone solution given to a boy, aged 5 and of average weight, prior to intubation for bronchography, prove to be a gross overdose.

A technique which I have found satisfactory in a small series of cases is as follows:

Age (years)	Approx normal weight (st)	Premedication (1 hr before op) 'Omnopon' (gr) + hyoscine (gr)
2-4	2-2½	1/12 + 1/600
4-10	2½-4½	1/6 + 1/400
10-12	4½-5½	1/6 + 1/300

Anæsthesia is induced with a mixture of 5% thiopentone and *d*-tubocurarine chloride. If age and body weight tally, 1 ml of thiopentone is given per year of age and 2 mg of tubocurarine per st body weight. The injection is given through a no. 19 'Vim' needle, and after insufflation with oxygen a special endotracheal tube with side tube (which I rightly or wrongly have called a Jones's tube) lubricated with 1% 'Anethaine' cream, is introduced into the trachea.

A Macintosh laryngoscope is used, and intubation is facilitated by the use of a stylette passing through a Cobbs union with the cap removed and three quarters of the length of the endotracheal tube. The pharynx is then packed off with gauze soaked in normal saline. Anæsthesia is maintained with nitrous oxide and oxygen (30%) given through a closed circuit. Respiration is assisted, and if the tidal exchange is inadequate at the end of the bronchography a small dose of neostigmine and atropine is administered.

This method has produced most satisfactory bronchograms. There is no explosion hazard, and the children have left the X ray department with brisk reflexes.

KERNICTERUS AND PREMATUREITY

SIR,—I was interested in the article of June 4 Dr Aidin and his colleagues, showing that the logical findings of "kernicterus" are not limited to Rh incompatibility. There is clinical evidence that Rh incompatibility is not the only cause of neonatal jaundice with neurological sequelæ. In a series of athetoids recently seen at this hospital, 31 had a history of severe neonatal jaundice. Of these, 19 were proved cases of Rh incompatibility. In 5 cases the Rh group of mother and child were compatible, in 4 others, whose blood was not investigated, the history did not suggest hæmolytic disease of the newborn, as the children were firstborn and the mothers had had no blood transfusion.

Children with other varieties of cerebral palsy will have a history of birth jaundice. In our series (to be published) only 7 out of 313 spastics and 23 cases had such a history, although a higher percentage of these children than of the athetoids had been premature babies. Nor is neonatal jaundice followed by athetoids found only among premature babies—only 5 of our 12 cases in which Rh incompatibility was not proved had birth weights of 5 lb 8 oz or under.

MEDICAL PEACE CAMPAIGN

SIR,—In 1937 a number of members of the medical profession, who were then associated with the late Prof J A Ryle and the late Dr Cecile Booyesen, initiated a Medical Peace Campaign. Its purpose will be obvious from its name. In 1939 the organisation discontinued its activities, after holding various meetings and publishing several reports and a number of issues of its bulletin. Since the close of the war it has been found difficult, for one reason or another, to assemble the members of the original committee. Finally, at a committee meeting held on May 19 last it was agreed to devote the remaining funds of the organisation to the relief of distress caused by war, and the sum of £65 has accordingly been donated to the Friends Relief Council with the request that it be used particularly for relief in China.

The committee appreciated that the cause of peace in the world is as much in need of support as ever it was in the past, but it expressed the view that its members could best serve that cause by associating themselves with one or other of the active organisations working for the purpose.

SELF-HELP OF UNDEREMPLOYED DOCTORS

SIR,—It is proposed to form a team—or several teams—of doctors, men and women who, like myself, are now without appropriate work or income. This team is going to offer its services to the National Health Service and will settle wherever it is most needed. This may be in an underdoctored area or in support of overworked outpatient departments. Its members are going to pool their resources of brains and skill, equipment, and money. They will acquire two houses and adapt the one for use as a central surgery with all facilities for diagnosis and outpatient treatment, the other as living quarters for themselves and their families. Work, service, and expenses will be shared by members and their wives (or husbands). So will the income. Each member will be required to practise as a general practitioner besides having a chance of using special experience. All must be prepared to share fully the risks and hardships of the first years. All will be stimulated by the knowledge that they are fighting common adversity by a combined effort, and that the success of their venture will lead to a decent livelihood earned by work of a high standard.

though these factors may not be wholly absent. Human frailties of this kind we shall always have, but what is now implied is worse than this, it is an error of thinking and method, a true quackery now to be introduced into medicine. In the last resort, such a censorship of hospital research work as is now adumbrated must be the responsibility of a single individual who will have to decide which research project is to be encouraged and which banned. However catholic his knowledge of the vast and variegated field of medical research, no one man can exercise this function rationally or equitably, and he must in undertaking it, become an administrative medical quack.

Moreover, the whole notion betrays an abysmal ignorance of the nature of clinical research. The spirit bloweth where it listeth, and no one can foretell of any research project, within wide limits, what possibilities of fruit it holds. Equally it cannot be foreseen what light a single piece of research may throw upon another and in independent one which covers the same field. We should not say to Goethe "there is no need for you to write a drama about Faust, for a very excellent one has already been written by Marlowe, and we really can't allow you to spend your time and our money this way, for after all, you are a State salaried official." Yet, *mutatis mutandis*, something as absurd and as intolerable as this is what is now proposed.

That a single central authority or person should be imposed upon us to decide which infant idea is to be strangled at birth and which conceded nourishment is a development which will take no wise spectator of what is happening to medicine by surprise, but even the most guleless of us must view it with grave disquiet.

F M R WALSHE

GENERAL ANÆSTHESIA FOR BRONCHOGRAPHY IN CHILDREN

SIR,—I have read with interest, in your issue of June 10, the technique employed by Dr Way and Mr James for anæsthetising children for bronchography, but I agree with Dr Wright (June 24) that the dosages of thiopentone mentioned may be dangerously large. I have known 0.5 g of 5% thiopentone solution given to a boy, aged 5 and of average weight, prior to intubation for bronchography, prove to be a gross overdose.

A technique which I have found satisfactory in a small series of cases is as follows:

Age (years)	Approx normal weight (st)	Premedication (1 hr before op) 'Omnipon' (gr) + hyoscine (gr)
2-4	2-2½	½ ₁₂ + ¼ ₆₀₀
4-10	2½-4½	½ ₈ + ¼ ₄₀₀
10-12	4½-5½	½ ₆ + ¼ ₃₀₀

Anæsthesia is induced with a mixture of 5% thiopentone and *d*-tubocurarine chloride. If age and body weight tally, 1 ml of thiopentone is given per year of age and 2 mg of tubocurarine per st body weight. The injection is given through a no. 19 'Vim' needle, and after insufflation with oxygen a special endotracheal tube with side tube (which I rightly or wrongly have called a Jones's tube), lubricated with 1% 'Anethane' cream, is introduced into the trachea.

A Macintosh laryngoscope is used, and intubation is facilitated by the use of a stilette passing through a Cobbs union with the cap removed and three quarters of the length of the endotracheal tube. The pharynx is then packed off with gauze soaked in normal saline. Anæsthesia is maintained with nitrous oxide and oxygen (30%), given through a closed circuit. Respiration is assisted and if the tidal exchange is inadequate at the end of the bronchography a small dose of neostigmine and atropine is administered.

This method has produced most satisfactory bronchograms. There is no explosion hazard, and the children have left the X-ray department with brisk reflexes.

L. S. MICHAELIS

THAMES POLLUTION

SIR.—The bacterial quality of the waters in the upper ches of the Thames is arousing acute controversy. Recently, several riparian local authorities expressed r apprehension at the high degree of bacterial urity in samplings from their reaches, especially in w of the potential menace to the health of bathers. I notified the Thames Conservators of their anxiety e Conservators, in their reply,¹ declared the Thames be no less safe now than in past years and said that re is no proof of any ill effects on anyone bathing in river. The Minister of Health apparently agrees h the views expressed by the Conservators.² Never- less it cannot be held that doubts have been resolved, d it is difficult on rational grounds to justify the nservators' contentions. Indeed, they appear to e confounded by a statement by the Metropolitan ater Board, in their forthcoming petition to Parlia- ment that the standard of purity of the raw waters of e Thames has deteriorated in recent years. It is stated authoritatively that the ordinary methods sewage purification effect no significant removal or struction of bacteria, and that effluents, even when high standard by chemical analysis (on which the nservators rely solely) are to be regarded, bacterio- gically, as little less dangerous than sewage.³ Hence, less sewage is treated by some form of disinfection, e pollution of a river will be proportional to the popula- m of the areas which drain into it. Both during and ce the war the populations in the townships round e upper reaches of the Thames have appreciably eased, and it is officially admitted that at more than e point the effluents being discharged into the river e highly objectionable.

A rise in population means, too, that while more amage goes into the river, more water is taken out. To eet the expanding consumer needs, both domestic and dustrial, the local water undertaking has abstracted istly larger amounts and a further demand is under tive consideration. Even this abstraction, however, is actional compared with the many more millions of illons daily removed from the upper reaches of the hames and supplied to London by the Metropolitan ater Board, and in this connection it is of interest at the newly opened unit at Walton works is to provide 1 additional 6 million gallons per day to the London ea.

The effect of these various factors must be to increase e bacterial density of the raw waters, and it is unlikely at bacterial self-purification plays a significant part here no great distances separate the points of sewage iffall. One may speculate as to the effect of the increas- g contamination in times of drought, and as to whether, timately, in face of certain new requirements, the quilibrium will overbalance to the detriment of the ashed waters provided by the water undertakings.

If it is true that, as the Conservators say, there is no roof of ill effects from bathing in the Thames, it is equally ue that there is no disproof. Even in authenticated aterborne epidemics it is extremely difficult to "prove"

the actual source of pollution, for the bacterium is rarely isolated, and the imputation of a particular water usually rests on circumstantial evidence, from which the best-favoured probability is selected. The Croydon epidemic of 1937 provides a classical example. A priori, I should regard it as likely that cases of illness have in fact been derived from bathing in the Thames. Since we know that raw river waters are bacteriologically unsafe—especially in certain localities—and that those who bathe and swim in these waters may ingest appreciable quantities, we shall not be far wrong in supposing that some of the illnesses attributed to waterborne infections have been contracted from the rivers. Naturally the existence of many alternative sources of infection, and the fact that the bathing public are only a minute cross-section of communities which are often widely dispersed, make it difficult to disprove that river water is often responsible, especially as most cases of illness thus derived would be treated empirically, and would not be notified or investigated.

It is not my intention either to overemphasise these dangers or to reject them. The Thames, however, is of growing importance as a source of water-supply, and to prevent its further deterioration the need for new anti-pollution measures, including sterilisation in some form⁴ should now be urgently considered.

MICHAEL ALBURY

THE THREE TYPES OF "NATURAL" DIURESIS

SIR.—Professor Borst and Dr de Vries, in their article last week, state that "the posterior-pituitary reaction affects the output of water and electrolytes in opposite directions," quoting Eggleton and Smith¹ and Sartorius and Roberts.² We feel that this statement may be misleading.

Eggleton³ observed a depression of chloride output in the urine accompanying a water diuresis, which continued as the rate of urine-flow fell. Eggleton and Smith⁴ suggested that the two factors, antidiuretic and chloride reabsorbing, while closely linked and probably both of pituitary origin, were not identical. The experiments of Sartorius and Roberts⁵ were performed on dogs.

We have recently shown⁶ that posterior-pituitary extracts do not increase the output of sodium and chloride in man. Whatever factor is responsible for the depression of chloride output during water diuresis, we do not believe that it is a posterior-pituitary one.

CHLORAMPHENICOL IN MUMPS

SIR.—In my limited experience, chloramphenicol has been so uniformly effective in the treatment of mumps that I am prompted to publish the results in the hope that others may give it a more extensive trial.

CASE 1.—A young man, aged 18, complained one evening of feverishness and malaise. Next morning one parotid gland, and that evening the other, became swollen. Temperature 38.3–38.5°C.

Chloramphenicol was started on the following day, with an initial dose of 2.5 g followed by 500 mg 5-hourly. Pain and temperature disappeared after 36 hours. Treatment was continued until 24 g had been given.

CASE 2.—A young man, aged 20, seen on the 5th day of the disease, had very painful bilateral parotid swelling, trismus and a temperature of 40°C. The same dosage of chloramphenicol was given. Pain and fever disappeared after 24 hours, and the swelling was gone in another 24 hours.

SELF-HELP OF UNDEREMPLOYED DOCTORS

SIR,—It is proposed to form a team—or several teams—of doctors, men and women who, like myself, are not without appropriate work or income This team is going to offer its services to the National Health Service and will settle wherever it is most needed This may be in an underdoctored area or in support of overworked outpatient departments Its members are going to pool their resources of brains and skill, equipment, and money They will acquire two houses and adapt them one for use as a central surgery with all facilities for diagnosis and outpatient treatment, the other as living quarters for themselves and their families Work service, and expenses will be shared by members and their wives (or husbands) So will the income Each member will be required to practise as a general practitioner besides having a chance of using special experience All must be prepared to share fully the risks and hardships of the first years All will be stimulated by the knowledge that they are fighting common adversity and a combined effort, and that the success of their venture will lead to a decent livelihood earned by work of a high standard

CASE 3—A boy of 10 came back from school vomiting repeatedly and complaining of headache. Temperature 38.5°C. Next morning his temperature was 40°C, and he had a slight tender swelling in the left parotid gland and difficulty in swallowing. Chloramphenicol 1.25 g was given in 1 hour, followed by 250 mg 5 hourly. Next morning the temperature was 38°C, the tenderness on the left side was practically gone but the right submaxillary gland was swollen. Next day this swelling had subsided and the temperature was normal.

CASE 4—Exactly two weeks after the boy of case 3, his mother was taken ill with malaise and dizziness but no pyrexia. In the course of the day her left parotid gland began to swell, and in the evening she could not open her mouth. Next morning the swelling became more apparent and was very tender. The temperature remained normal, and she volunteered that when she was ill her temperature seldom rose above normal. Chloramphenicol was given in the evening—2.5 g in the course of 2 hours, and 0.5 g 5 hourly thereafter. Owing to dizziness and loss of accommodation, the dosage was reduced after 15 hours to 0.5 g 8 hourly. In all, 7 g was given, after which the drug had to be withheld. The temperature never rose above 37.2°C. On the 3rd day, the right submandibular gland was affected. The pain disappeared on the 5th day, swelling subsided on the 8th day.

This case appeared to be mild from the start, and it is difficult to evaluate the effect of chloramphenicol on it.

G H DONALD

EMPLOYMENT FOR THE TUBERCULOUS

SIR,—It is generally accepted among tuberculosis workers that the risk of contracting tuberculosis is less in a modern sanatorium than in many general hospitals and factories. On the other hand, the Joint Panel on the Resettlement of the Tuberculous, a body representing the National Advisory Council on the Employment of the Disabled and the Tuberculosis Standing Advisory Committee of the Central Health Services Council, have recommended that infectious tuberculous persons seeking ordinary employment should be submitted to jobs by the Ministry of Labour only if they agreed to the dis closure of their disability to the prospective employer.

At the present time there is no unified policy regarding the management of the persistently sputum positive case of pulmonary tuberculosis. The National Health Service Act has concentrated our attention on the treatable case—the one in which there is a good possibility of sputum conversion being obtained. In spite of this, large numbers of patients are discharged from sanatoria each year with a positive sputum. A further number with a positive sputum are never admitted to sanatorium since they would not benefit from active treatment. In consequence, around 25% of the cases of pulmonary tuberculosis known to the chest clinics and who are not in hospital have a positive sputum. It can be seen, therefore, that the group of infectious cases of tuberculosis is not a small one.

What are we to do with them? The recommendation that the disablement resettlement officers of the Ministry of Labour should inform the prospective employer of the patient's disability means that very few of this group will obtain suitable employment. Instead, many will obtain employment by their own efforts—employment which may not be suitable for their condition and where the working conditions may be conducive to the spread of infection.

If it is felt that the infectious case of tuberculosis is a menace, then segregation is the answer and we should press for this policy to be implemented. As much, if not more, damage can be done by these people frequenting cinemas and other places of entertainment as could be done at work.

On the other hand, if it is accepted that nursing known infectious cases of tuberculosis is safer than working in general hospitals, then we cannot regard the group of patients as a menace. Surely then, it would be better to allow infectious cases of tuberculosis to be submitted for ordinary employment by the Ministry of Labour, provided that the chest physician is satisfied that the patient has been taught and observes the usual hygienic precautions taught in hospital.

As a result of consultation between the disablement resettlement officer and chest physician, the patient would be more likely to obtain a situation which is not deleterious to his condition, and this would allow consideration to be given to the conditions under which the patient would be working—for example, whether the factory employs many young people from rural areas, and whether resistance to infection is likely to be lowered by such factors as fatigue from long travelling and unsatisfactory meals.

CEREBELLAR SYNDROME FOLLOWING SODIUM AMYTAL

SIR,—In the following three cases, seen lately within ten days of each other, 'Sodium amytal' gave rise to cerebellar dysfunction.

CASE 1—The first case was a spinster, aged 48 who some months previously had received electroconvulsive therapy for endogenous depression. She had lost her suicidal tendencies but still had symptoms very similar to those of the post concussional syndrome. Apart from headache, the most disabling symptom was extreme hyperacusis, and since the patient lives in a bungalow in a densely populated area with a high birth rate, her state was particularly unhappy. To make her lot more tolerable, I prescribed sodium amytal gr 3 at night, and gr 1 if necessary during the afternoon when the children of the neighbourhood erupted from school with screams of delight.

After she had been taking this dosage for about a fortnight, she came for a follow up consultation. She collapsed on the threshold. There was no loss of consciousness, no pallor, no slowing of the pulse. I placed her in an armchair and made a mental note of "hysteria." I thought that this sudden "paraplegia" was an unconscious protest at my requiring her to come across the city, it seemed unwise to examine the central nervous system lest the symptoms became fixed, so I contented myself with discussing her current domestic difficulties and I advised her to continue sodium amytal in the same dosage.

CASE 2—Three days later I visited a man, aged 60, who had lately had a sudden severe attack of precordial pain, which had been tentatively diagnosed by his doctor as of cardiac origin. Actually, the source of this pain was proved to be fibrositic. For many years this man had had nosophobia, his particular dread being of the chest. The suggestion that he might have angina had dire results, he developed an acute anxiety state with raised blood pressure.

I put him on sodium amytal gr 3 four times a day. For a week this had excellent results—he was sleeping well, his

EMPLOYMENT FOR THE TUBERCULOUS

SIR,—It is generally accepted among tuberculosis workers that the risk of contracting tuberculosis is less in a modern sanatorium than in many general hospitals and factories. On the other hand, the Joint Panel on the Resettlement of the Tuberculous, a body representing the National Advisory Council on the Employment of the Disabled and the Tuberculosis Standing Advisory Committee of the Central Health Services Council, have recommended that infectious tuberculous persons seeking ordinary employment should be submitted to jobs by the Ministry of Labour only if they agreed to the disclosure of their disability to the prospective employer.

At the present time there is no unified policy regarding the management of the persistently sputum positive case of pulmonary tuberculosis. The National Health Service Act has concentrated our attention on the treatable case—the one in which there is a good possibility of sputum conversion being obtained. In spite of this, large numbers of patients are discharged from sanatoria each year with a positive sputum. A further number with a positive sputum are never admitted to sanatorium since they would not benefit from active treatment. In consequence, around 25% of the cases of pulmonary tuberculosis known to the chest clinics and who are not in hospital have a positive sputum. It can be seen, therefore, that the group of infectious cases of tuberculosis is not a small one.

What are we to do with them? The recommendation that the disablement resettlement officers of the Ministry of Labour should inform the prospective employer of the patient's disability means that very few of this group will obtain suitable employment. Instead, many will obtain employment by their own efforts—employment which may not be suitable for their condition and when the working conditions may be conducive to the spread of infection.

If it is felt that the infectious case of tuberculosis is a menace, then segregation is the answer and we should press for this policy to be implemented. As much, if not more, damage can be done by these people frequenting cinemas and other places of entertainment as could be done at work.

On the other hand, if it is accepted that numerous known infectious cases of tuberculosis is safer than working in general hospitals, then we cannot regard the group of patients as a menace. Surely then, it would be better to allow infectious cases of tuberculosis to be submitted for ordinary employment by the Ministry of Labour, provided that the chest physician is satisfied that the patient has been taught and observes the usual hygienic precautions taught in hospital.

As a result of consultation between the disablement resettlement officer and chest physician, the patient would be more likely to obtain a situation which is not deleterious to his condition, and this would allow consideration to be given to the conditions under which the patient would be working—for example, whether the factory employs many young people from rural areas and whether resistance to infection is likely to be lowered by such factors as fatigue from long travelling and unsatisfactory meals.

CEREBELLAR SYNDROME FOLLOWING SODIUM AMYTAL

SIR,—In the following three cases, seen lately within ten days of each other, 'Sodium amytal' gave rise to cerebellar dysfunction.

CASE 1—The first case was a spinster, aged 48, who some months previously had received electroconvulsive therapy for endogenous depression. She had lost her suicidal tendencies but still had symptoms very similar to those of the post-concussional syndrome. Apart from headache, the most disabling symptom was extreme hyperacusis, and since the patient lives in a bungalow in a densely populated area with a high birth rate, her state was particularly unhappy. To make her lot more tolerable, I prescribed sodium amytal gr 3 at night, and gr 1 if necessary during the afternoon when the children of the neighbourhood erupted from school with screams of delight.

After she had been taking this dosage for about a fortnight she came for a follow-up consultation. She collapsed on the threshold. There was no loss of consciousness, no pallor, no slowing of the pulse. I placed her in an armchair and made a mental note of "hysteria." I thought that this sudden "paraplegia" was an unconscious protest at my requiring her to come across the city. It seemed unwise to examine the central nervous system lest the symptoms became fixed, so I contented myself with discussing her current domestic difficulties and I advised her to continue sodium amytal in the same dosage.

CASE 2—Three days later I visited a man, aged 60, who had lately had a sudden, severe attack of precordial pain which had been tentatively diagnosed by his doctor as of cardiac origin. Actually, the source of this pain was proved to be fibrositic. For many years this man had had nosophobia, his particular dread being tabs. The suggestion that he might have angina had dire results, he developed an acute anxiety state with raised blood pressure.

I put him on sodium amytal gr 3 four times a day. For a week this had excellent results—he was sleeping well, his

1 Donald G. H. *J. Canad. Diet. Ass.* December 1940
2 Ziegelmayer W. *Z. Ernähr.* 1931 1 25
3 Horner A. *J. Soc. chem. Ind. Lond.* 1939 58 86

blood pressure dropped by 50 mm Hg, and he was no longer shocked with his heart. But to my annoyance he spoilt the satisfactory picture of recovery by complaining of a new symptom—sudden collapse while walking. Twice while walking in the town he suddenly felt giddy and had to sit down. His legs gave way beneath him, objects tended to wobble, and he had a rather severe occipital headache, but no nausea or tinnitus. Examination showed no nystagmus, and his phobia about tables he has always had some reinforcement, and to elicit the knee jerks some reinforcement has been needed.

Once again I attributed the "attacks" to psychogenic causes. I argued that this man, with his fear of angina as collapsing out of doors as a defence against exercise that might strain a heart he believed to be vulnerable reiterated my assurances about the state of his myocardium, and reduced the dose of sodium amytal to gr 2 a day.

CASE 3.—The next day I visited a woman, aged 50, the headmistress of a school. She is of manic-depressive temperament, and some years ago was operated on for exophthalmic goitre. She was sleeping badly, feeling "end-of-the-worldish," and bothered by a possessive attachment formed by a member of her staff. I prescribed sodium amytal gr 3 at night. Some weeks later she reported that she felt extremely weak in the legs that it took her ten minutes to walk 200 yards to the post-box, and that she feared to cross the road and would not go out alone lest she collapsed.

Electromyographic studies have shown that sodium amytal lowers tone.¹ In cats the lethal dose varies widely, and some which partly recovered had a persistent syndrome of altered reflexes and abnormal posture and gait, pathological changes were confined to the Purkinje cell layer in the cerebellum.²

With these findings in mind, I reviewed the 3 cases.

Re-examination of the 1st patient showed that she had very flabby calf muscles, and the ankle jerk on the left side could not be elicited. There was no nystagmus and no incoördination in the upper limbs. Sodium amytal was replaced by a bromide and soluble barbitone mixture. A week later she was free of vertigo and had not collapsed again.

The 2nd patient was also found to have very poor muscle tone in the calves, both ankle jerks were, however, present. There was no nystagmus and no incoördination in the upper limbs. Sodium amytal was gradually replaced by phenobarbitone and the patient has not collapsed again.

The 3rd patient had no evidence of altered tendon reflexes and no incoördination or ataxia, but muscle tone was poor. Sodium amytal was stopped and phenobarbitone prescribed. In less than three days she was walking alone with confidence, and had lost the vertigo.

The idiosyncrasy in these cases may have been associated with hepatic dysfunction, which is said to increase toxicity.³ Sodium amytal belongs to the group of barbiturates which are chiefly broken down in the liver (though not to the same extent as thiopentone and hexobarbitone) only 3–5% is excreted in the urine, compared with 25% of phenobarbitone and 30% of allobarbitone.

Of the 3 cases described here, the 1st had no history or evidence of hepatic disorder, the 2nd was known to have gall stones and had had several attacks of biliary colic, and the 3rd may be presumed to have had hepatic dysfunction since hyperthyroidism is usually associated with defective liver function.⁴

This series illustrates some of the difficulties of assessing the origin of symptoms in patients with psychiatric or psychosomatic disorders. It is easy to accept as functional, symptoms which actually have an organic cause, and but for the coincidence of 3 cases arising within a fortnight, this syndrome of cerebellar dysfunction following administration of amytal might easily have been overlooked.

TRAVELLING EXHIBITIONS ON CLEANLINESS

SIR—May I assure Dr Forster, who wrote last week, that the Central Council for Health Education is dealing with the problem of its present stands being rather cumbersome.

By September, 250 light frames, on which exhibition pieces can be displayed, will be available to local health authorities, making treble the number of stands in circulation. These stands have been designed so that they can, if necessary, be carried in a private car, and assembled and dismantled in a few minutes. Reports from medical officers of health indicate that where stands have been shown in factories, they have proved very popular, and the Council hopes that more approaches to this type of audience will be arranged.

INJURY FROM ELECTRIC WASHING-MACHINES

SIR,—In the U.S.A. housewives and children are not uncommonly injured by automatic washing machines. In this city a woman had her arm pummelled for half an hour before she freed it by the slow process of dragging the machine to the switch, which she turned off.

The injury may be severe, and may be followed by extensive loss of skin through damage to the cutaneous blood supply. Injury to the muscles of the arm and forearm may seriously limit the activity of the fingers and hands. The condition calls for prompt treatment in hospital. Immediate application of an efficient pressure bandage prevents collection of subcutaneous exudate. Fine judgment is needed in the use of the pressure bandage and of rest, the time for starting active treatment must be chosen with care because oedema may recur. Though at first the damage may appear very slight, ultimately destruction may be great.

In the late stages the victim presents with an enormous subcutaneous hematoma, extending over the whole length of the forearm. There may be areas of skin necrosis and associated infection, and severe oedema and puffiness develops in the hand, probably owing to obstruction of the lymphatic channels draining this region. There is an area of relatively normal appearance around the wrist where the skin seems to be least affected, and the whole appearance is somewhat akin to that of an inverted champagne bottle.

Fortunately, in the British Isles domestic washing machines with electrically operated rollers are rare, so the condition is unlikely to be seen, but a safety device should be installed on any machines that have automatic rollers.

J D WADE

ANOXIA IN THE FETUS AND NEWBORN

SIR,—In your leading article last week you perpetuate an argument concerning periodic breathing which does not seem to have any justification. You say

"The alternating hyperpnoea and apnoea commonly seen in premature infants is a characteristic of 'mountain sickness' and gives place to regular respirations in an oxygen enriched atmosphere. Premature infants with periodic respiration should therefore be given oxygen."

This suggests that the periodic breathing of the premature infant has the same physiological basis as the anoxic periodic breathing of mountain sickness, and neglects facts of fundamental importance. These are (1) that periodic breathing is almost as common in the full term as in the premature infant, (2) that while this periodic breathing is occurring in the newborn, generally there is no cyanosis, which sharply distinguishes

CASE 3—A boy of 10 came back from school vomiting repeatedly and complaining of headache. Temperature 38.5°C. Next morning his temperature was 40°C, and he had a slight tender swelling in the left parotid gland and difficulty in swallowing. Chloramphenicol 1.25 g was given in 1 hour, followed by 250 mg 5 hourly. Next morning the temperature was 38°C, the tenderness on the left side was practically gone but the right submaxillary gland was swollen. Next day this swelling had subsided and the temperature was normal.

CASE 4—Exactly two weeks after the boy of case 3, his mother was taken ill with malaise and dizziness but no pyrexia. In the course of the day her left parotid gland began to swell, and in the evening she could not open her mouth. Next morning the swelling became more apparent and was very tender. The temperature remained normal, and she volunteered that when she was ill her temperature seldom rose above normal. Chloramphenicol was given in the evening—2.5 g in the course of 2 hours, and 0.5 g 5 hourly thereafter. Owing to dizziness and loss of accommodation, the dosage was reduced after 15 hours to 0.5 g 8 hourly. In all, 7 g was given, after which the drug had to be withheld. The temperature never rose above 37.2°C. On the 3rd day, the right submandibular gland was affected. The pain disappeared on the 5th day, swelling subsided on the 8th day.

This case appeared to be mild from the start, and it is difficult to evaluate the effect of chloramphenicol on it.

Calro

P GHALIOUNGUI

WATER AS A NUTRIENT

SIR,—In his letter of June 10, Mr Bullock writes "Moreover, in cooking, much of this calcium might go out of solution, forming a deposit on cooking utensils and becoming unavailable."

Various workers have found that calcium is actually deposited on vegetables during cooking, thereby making more calcium available for consumption.¹⁻³ The following figures are reported by Donald¹

	Calcium (mg per 100 g)	
	Raw	Boiled
Beetroot	21	27
Cauliflower	19	23
Potato	9	16

Notes and News

HARVEIAN SOCIETY OF LONDON

HELD at Grocers' Hall on June 29, the Buckston Browne and Grav Hill dinner of this society was attended by 165 members and guests.

THE MARQUESS OF LINLITHGOW proposing The Society called William Harvey's association with Bacon, and Bacon's injunction, in his *Requiem of Health*

"forget not to call as well the best acquainted with your bodie, as the best reputed of for his faculty"

The position of the family doctor was now in jeopardy, and it was doubted whether the public had yet realised how much was at stake. Prevention of disease—said to be our aim—required early recognition of departures from normal. Bacon had rightly valued the general practitioner as the man "best acquainted with my body." Don't leave the general practitioner in isolation," said Lord Linlithgow, let him keep abreast of progressive medicine, enable him to use the daily increasing armoury of remedies, give him time to think as well as to work, and make this branch one that will attract the best men of their year. As a patient he added, he was anxious that doctors should be properly remunerated, and that no practitioner to earn his bread and butter, should be driven to look after more patients than he could care for properly. But he felt that everyone in the health service should bear constantly in mind that patients are the people most concerned in this affair: the welfare of the patient should be the lodestone to which all should continually respond.

Dr R. R. TRAIL, responding as president said that the profession could hardly hear too often about its responsibilities: perhaps doctors were not always aware how much faith was placed in them. He went on to compare Harvey's day with the present. When Harvey was alive, man was still the paragon of animals and the marvel of the world—not an atom in universal space. There were brawls in the streets, and cruelty was everywhere: public executions were the favourite spectacle and 200 witches were burnt in a year near Papworth. Heresy and treason were synonymous, books were few and heavy, people did without glass bottles or windows or comfortable chairs. But had we really advanced so far since then? Had happiness increased? Was bubonic plague worse than the modern disease called frustration which was so grave a threat to the democratic way of life? Today there was mass production, but people were not prepared to sink their individualities. Tons of aspirin would not make up for loss of faith and he expected a continuing increase of psychosomatic disorders—from eczema to pulmonary tuberculosis. The answer lay with the medical profession, and it would be found when the problem was attacked with the same pertinacity as bubonic plague.

Responses for The Guests (skilfully marshalled by Dr M. C. W. LONG) came from Lieut. General Sir FREDERICK BROWNING and Dr RUSSELL BRAIN, F.R.C.P., who said that the dinner was being held 300 yards from where Harvey lived, overlooking St. Lawrence Poultry, 300 years ago. What was now, Dr Brain asked, the state of the circulatory system of medicine? In the consultants we had some of the large vessels, and in the peripheral circulation we had the general practitioners. Most of the important things in the body happened in the periphery, and we should learn from Harvey that what affected one part of the circulation affected the whole. We must make of general practice a calling in which we should wish our sons to take part.

THE SCOTS HAE A WORD FOR IT

IN one of the poems in his collection of *Gangrel Verses* Dr William Barr describes his delight in having two kinds of speech. As he puts it: it's fine "tae hae yer pockets on vae side, Yer pooches on the ither." He has applied this system of balanced contrasts throughout his life. Not only has he kept Lowland Scots at the tip of his English speaking tongue, but he has crossed the Border to live in England without losing any of his native flavour. As a medical officer of health he has no doubt read a wealth of official rules and regulations but he has not lost his knack of describing simple occasions with sincerity and humour. His little book will please not only his fellow Scots but also all those who consider "peely wally" an apt description of post-influenzal depression.

1 Glasgow William MacLellan. 1950 Pp 72 7s 6d

THE NATIONAL CHURCH

Trollope, in *Phineas Redux*, makes men speak of disestablishment of the Church as a thing bound to come in spite of the clergy. Politicians were concerned mainly to ensure that the measure should be passed by the appropriate party. Whether or not this mirrored any general opinion of Trollope's day, it reveals a great difference from modern feeling.

Then, as now, bishops of the Church of England were nominated by the Prime Minister, convocations could not meet or make canons without the licence of the Crown, and on an appeal from the ecclesiastical courts the doctrine of the Church was interpreted by State judges appointed by the State. But in those days people and Parliament were nearly all Anglicans and it could be said that they, and the judges they appointed, represented the laity of the Church. This no longer holds true, as the Archbishop of York puts it in a scholarly and temperate book,¹ a large number of members of Parliament "dislike institutional religion and certainly would not commit themselves to the definite acceptance of the Christian faith."

In short Parliament no longer represents the Anglican laity, yet it still retains traditional powers over the life of the Church. How cavalierly this may be exercised was shown, in 1927 and 1928, by the rejection, in a few hours, of the revision of the Prayer Book, on which informed and able churchmen had worked for many years. One argument used then was that to modernise the Prayer Book was to tamper with the nation's traditions (though anyone who reads the two versions can see how jealously tradition was guarded), and it is possible—even probable—that a move for disestablishment would rouse similar indignation in many who take no interest in the Church's activities. The case for disestablishment comes nowadays from inside the Church, and the arguments for and against it are discussed in great detail in this book.

Those who have little knowledge of modern Church history will be startled to find how greatly the whole organisation of the Anglican community is hampered and frustrated by the present laws, and those who think the Church inept in using its great opportunities will find the cause of much that offends them in restrictions, regulations, and customs which make ordinary bureaucracy look like Liberty Hall.

The Archbishop does not favour disestablishment except in the last resort but he puts a strong case for reforms which would liberate the Church to fulfil its proper duties to society and to direct its own spiritual life—notably that the dioceses should have a recognised right to be consulted in the choice of a new bishop, though the Prime Minister would still nominate and the Crown appoint, that the Church provided it had gained the agreement of most churchmen and lay members, should be able to revise its forms of worship without a debate in Parliament, that canon law should be revised by the Church itself and that Church courts should be reformed, especially that the final court of appeal, which—though it has to settle questions of doctrine—is composed entirely of judges, should be replaced by a new court on which bishops are represented. If it fails to gain these reforms, he believes the Church should ask for disestablishment.

Society for the Study of Addiction

At a meeting of the society to be held at 11, Chandos Street, London W 1, on Tuesday, July 18, at 4 P M, Mr L D Macleod, B.Sc., will speak on Biochemistry and Alcoholism

Tuberculosis Refresher Course

The Tuberculosis Educational Institute is arranging a refresher course on the pathology and immunology of tuberculosis, to be held at Oxford on September 19-22. Applications should be addressed to the institute's secretary Tavistock House North Tavistock Square, London, W C 1

Osler Club

At this society's annual dinner, to be held at the South Kensington Hotel, Queen's Gate Terrace, London, S W 7, at 7 45 P M on July 12, the Oslerian oration will be delivered by Sir Henry Souttar. The society's hon. secretary is Dr M J Lunnett, 70 Shooter's Hill Road, London, S E 3

Medical Society for the Study of Venereal Diseases

This society's annual general meeting will be held on Friday, July 28, at 7 30 P M, at 11, Chandos Street, London, W 1. Afterwards, Dr Robert Lees, the retiring president, will deliver his presidential address, entitled Random Reflections. Dr Mary Michael Shaw will be installed as the new president.

Threatened Withdrawal of Chemists in Northern Ireland

The *Times* (July 1) reports that Northern Ireland chemists have given three months' notice of resignation from the health service in view of the action of the ministry of health and local government in imposing a deduction of 8% from the total payable to them for drugs and containers supplied and for professional services.

Medical Conference at Verona

Two Nobel laureates, Prof G Domagk and Prof E Moniz are taking part in the International Medical Week which is being held at Verona from July 20 to 30. Other speakers will include Mr T Holmes Sellors, Mr C Brock, and Dr R P Liston (London), Prof H Olivecrona and Prof C Crafoord (Stockholm), Dr A Waksman (New Brunswick), and Dr D B Dill (Maryland). Further particulars may be had from Prof Luigi Barchi, Pescheria Vecchia, 6 Verona, Italy.

Medical Insurance Agency

The annual meeting of the Medical Insurance Agency was held in London on June 23. The report for 1949 disclosed a record amount of service to the profession (life insurance negotiated by the agency totalled about £2,976 000), a record total of rebates of premium, and a record profit available for medical charities. New covenants were entered upon with the Royal Medical Benevolent Fund, the Royal Medical Foundation of Epsom College, and the Benevolent Fund of the British Dental Association. Dr James Fenton was re-elected chairman, and Dr Henry Robinson hon. secretary, of the committee of management.

Reciprocal Health Service Arrangements with Jersey and Guernsey

A reciprocal health service agreement has been concluded between the Ministry of Health and the Department of Health for Scotland on the one hand and the States of Jersey and Guernsey on the other. Under the agreement, Channel Islanders may use the facilities of the National Health Service (other than those relating to mental health and mental deficiency) free of charge and arrangements will be made for the admission of Channel Islanders to hospitals in Great Britain where adequate hospital facilities do not exist in Jersey or Guernsey. As facilities are limited in the Channel Isles, and there is no free National Health Service there, a complete range of health service facilities cannot be offered to the large number of tourists from Great Britain who visit the Channel Islands each summer. Jersey will, therefore, provide free inpatient and outpatient hospital treatment, but no family doctor service. Guernsey will provide free inpatient hospital treatment and a family doctor service. No dental or ophthalmic treatment is to be provided by the States of either island. All free facilities provided by the States are for tourists from Great Britain only and not for those who become resident in the islands. The States are to pay the Ministry of Health for certain accommodation in mental deficiency institutions in England and for some laboratory facilities.

Mental Health Conference

An informal conference to discuss better local co-ordination of home and hospital services in the sphere of mental health is to be held at the Town Hall, Salford, on July 14, at 2.30 P M.

International Congress of Paediatrics

The sixth international congress of paediatrics is to be held at Zürich from July 24 to 28. The congress proper will be preceded and followed by two day courses of postgraduate lectures. The English speakers will include Prof J C Spence, Dr P L Mollison, Dr John Murray, Dr R R A Coombs, Dr C E Dent, Dr Mildred Creak, Prof A St G Huggett, Dr Cicely Williams, Prof D R MacCallum, Prof Norman Capon, Dr Philip Evans, Dr C D S Agar, Dr Denis Hill, Prof J M Smellie, Prof Dorothy Rust, Prof Norman Dott, Dr F J Miller, Dr W R F Cole, Dr F O MacCallum, Mr T Holmes Sellors, Dr J E Hutchison, Dr Martin Bodian, Dr Bernard Schlesinger, and Prof A A Moneroff.

The 1950 edition of the Register of Chiropodists has now been published. Medical practitioners may obtain a copy without charge on application to the registrar, Board of Registration of Medical Auxiliaries, Tavistock House North Tavistock Square, London, W C 1.

In view of the very large demand for copies, the trustees of the Carnegie United Kingdom Trust have decided to put on sale to the public Dr Stott's report on *Delinquency and Human Nature*, which was originally printed for private circulation only (see *Lancet*, 1950, i, 903). The charge which is no more than a nominal one, and includes postage, is 5s in the sterling area or \$1 in America. Orders, with remittances, should be sent direct to the trust, Dunfermline, Fife, Scotland. The report is not available through trade channels.

CORRIGENDUM *Kernicterus and Prematurity*—In the penultimate paragraph of Dr Gerrard's letter last week (p 35), line 11 should read "but if this is so it would explain why hypoglycaemia."

Births, Marriages, and Deaths

BIRTHS

ARCHER—On June 25 at Harrow the wife of Dr R M Archer—a daughter.
GRAHAM—On June 27, in London the wife of Dr W V Graham—a daughter.
HOWELL—On June 23 in London the wife of Dr David Howell—a son.
HOYTE—On June 28 the wife of Dr D A N Hoyte—a daughter.
JOEL—On June 24 in London the wife of Dr L J R Joel—a son.
JEFFERIES—On June 30 at Exeter, the wife of Dr Derek Jeffries—a daughter.
KENDALL—On May 31, in Oxford the wife of Dr A C Kendall—a son.
REID—On June 24 in London the wife of Mr D A C Reid, F.R.C.S.—a son and a daughter.
RIDDELL—On June 23 in London the wife of Dr Roland RiddeLL—a son.
TULLY—On June 24 at Wigan the wife of Dr D R Tully—a daughter.

MARRIAGES

DUFF—HEATON SMITH—On June 24 at Gerrards Cross Alexander Dewar Duff M.B. to Audrey Heaton Smith.
FISH—HODGE—On June 23 in London Eric Wilfred Fish C.B.E., M.D. to Myfanwy Hazel Bruce Hodge.
GRAVES—TWISLETON WYKHAM FIENNES—On June 22 at East Worlham, Alton John Ley Graves M.D., to Elizabeth Margaret Twisleton Wykham Fienes.
RYDER RICHARDSON—HERBERT—On June 24, at Stone, David Edward Ryder Richardson M.R.C.S., to Sonia Herbert.

DEATHS

DORE—On June 27 Samuel Ernest Dore M.A. M.D. Camb. F.R.C.P.
GLEED—On June 28 in London Seymour Richard Glead M.R.C.S. aged 68.
JOHNSTONE—On June 24 at Lockerbie George Johnstone, M.R.C.S. Edin.
LEWERS—On June 26 at Ilfracombe Hugh Bunnell Lewers D.S.O. O.B.E. M.B. Melb.
MILL—On June 9 in Liverpool Felix Oswald Newton Mell C.I.E., M.B. Edin. lieut.-colonel I.M.S. retd. aged 80.
POLSON—On June 27 at Milford-on-Sea James Ronald Polson M.D. Birm. aged 91.
QUIRKE—On June 22 in London John Joseph Quirke M.R.C.S. aged 82.
SMITH—On June 22 at Hindhead Gilbert Smith, M.D. Durban F.R.C.S. aged 75.
WARD—On June 29, John Forbes Ward, M.D. Manc. F.R.C.P.

Society for the Study of Addiction

At a meeting of the society to be held at 11, Chandos Street, London, W 1 on Tuesday July 18, at 4 p m, Mr L D Atledge B Sc, will speak on Biochemistry and Alcoholism

Tuberculosis Refresher Course

The Tuberculosis Educational Institute is arranging a reference course on the pathology and immunology of tuberculosis, to be held at Oxford on September 19-22. Applications should be addressed to the institute's secretary, Tavistock House North, Tavistock Square, London, W.C.1

Oster Club

at this society's annual dinner, to be held at the South Kensington Hotel, Queen's Gate Terrace, London, S W 7, on July 12, the Oslman oration will be delivered by Sir Henry Soutar, The Society's Hon. Secretary, 20, Shooter's Hill Road, London, S E 3.

Medical Society for the Study of Venereal Diseases

This society's annual general meeting will be held on Friday, July 28, at 7 30 p m, at 11, Chandos Street, London, W1. Afterwards, Dr Robert Lees, the retiring president, will deliver his presidential address, entitled Random Reflections. Dr Mary Michael Shaw will be installed as the new president.

Threatened Withdrawal of Chemists in Northern

The *Times* (July 1) reports that Northern Ireland economists have agreed these months' not to rejoin the pound sterling. The government has agreed a 5% cut in the military and a 10% cut in the health and other services. The government has agreed a 5% cut in the military and a 10% cut in the health and other services. The government has agreed a 5% cut in the military and a 10% cut in the health and other services.

Medical Conference at Verona

Two Nobel laureates, Prof. G. Domagala and Prof. B. Almon, are taking part in the International Medical Week which is being held at Verona from July 20 to 30. Other speakers will include Mr. T. Holmes Sellers, Mr. C. Brock, and Dr. R. F. Easton (London), Prof. H. Oliverson and Prof. C. Crafoord (Stockholm), Dr. A. Waksman (New Brunswick), and Dr. D. B. Dill (Maryland). Further participation may be had from Prof. Luigi Barchi, Peschiera Vecchia, Verona, Italy.

Medical Insurance Agency

The annual meeting of the Medical Insurance Agency was held in London on June 23. The report for 1949 disclosed a record amount of service to the profession (life insurance negotiated by the Agency totalling about £2,976,000), a record total of rebates of premium, and a record profit available for medical charities. New covenants were entered upon with the Royal Medical Benevolent Fund, the Royal Medical Foundation of Ipswich College, and the Benevolent Fund of the British Dental Association. Dr James Kenton was re-elected chairman, and Dr Henry Robinson hon secretary, of the committee of management.

Reciprocal Health Service Arrangements with Jersey and Guernsey

and Guernsey

A reciprocal health service agreement has been concluded between the Ministry of Health and the Department of Health for Scotland on the one hand and the States of Jersey and Guernsey on the other. Under the agreement, Channel Islanders may use the facilities of the National Health Service (other than those relating to mental health and mental sub-specialency) free of charge and arrangements will be made for the admission of Channel Islanders to hospitals in Great Britain where adequate hospital facilities do not exist in Jersey or Guernsey. As facilities are limited in the Channel Islands, and there is no free National Health Service there, a complete range of health services cannot be offered to the large number of tourists from Great Britain who visit the Channel Islands each summer. Jersey will, therefore, provide free inpatient and outpatient hospital treatment, but not family doctor service. Guernsey will provide free non-patient hospital treatment and a family doctor service. States of either island will the facilities provided by the States are for tourists from Great Britain only and not for those who become resident in the islands. The States are to pay the Ministry of Health for certain accommodation in inpatient deficiencies in England and for some laboratory facilities.

Mental Health Conference

An informal conference to discuss better local conditions of home and hospital services in the sphere of mental as to be held at the Town Hall, Salford, on July 14, at 2.30 p.m.

Mental Health Conference

International Congress of Paediatrics

International Congress of Paediatrics

The sixth international congress of paediatrics is to be held from July 24 to 28. The congress proper will proceed and followed by two day courses of lectures. The English speakers will include Prof. J. Spence, Dr. P. L. Allison, Dr. John Murray, Dr. R. B. Coombs, Dr. C. E. Dent, Dr. Alured Greig, Prof. J. H. Huggate, Dr. Cicely Williams, Prof. D. R. MacCallan, Norman Capon, Dr. Philip Evans, Dr. C. D. S. Dr. Denis Hui, Prof. J. M. Smellie, Prof. Dorothy R. Prof. Norman Dole, Dr. F. J. Miller, Dr. W. R. F. Cap. Dr. F. O. MacCallum, Mr. T. Holmes Soltors, Dr. J. H. Hutcheson, Dr. Martin Bodian, Dr. Bernard Schlesinger, Prof. A. Monodoff

Tavistock Square, London, W C 1

In view of the very large demand for copies, the trustees of the Carnegie United Kingdom Trust have decided to put the *Human Nature*, which was originally printed for private circulation only (see *Lancet*, 1950, i, 903). The charge, which is no more than a nominal one, and includes postage, is 5s in the sterling area or \$1 in America (Duke of Edinburgh, Ltd., Scotland). The report is not available through trade channels.

Society for the Study of Addiction

At a meeting of the society to be held at 11, Chandos Street, London W 1, on Tuesday, July 18, at 4 P.M., Mr L D Macleod, B.Sc. will speak on Biochemistry and Alcoholism

Tuberculosis Refresher Course

The Tuberculosis Educational Institute is arranging a refresher course on the pathology and immunology of tuberculosis, to be held at Oxford on September 19-22. Applications should be addressed to the institute's secretary, Tavistock House North, Tavistock Square, London, W C 1

Osler Club

At this society's annual dinner, to be held at the South Kensington Hotel, Queen's Gate Terrace, London, S W 7, at 7.45 P.M. on July 12, the Oslerian oration will be delivered by Sir Henry Souttar. The society's hon. secretary is Dr M J Lunnett, 70, Shooter's Hill Road, London, S E 3

Medical Society for the Study of Venereal Diseases

This society's annual general meeting will be held on Friday, July 28, at 7.30 P.M., at 11, Chandos Street, London, W 1. Afterwards, Dr Robert Lees, the retiring president, will deliver his presidential address, entitled *Random Reflections*. Dr Mary Michael Shaw will be installed as the new president.

Threatened Withdrawal of Chemists in Northern Ireland

The *Times* (July 1) reports that Northern Ireland chemists have given three months' notice of resignation from the health service in view of the action of the ministry of health and local government in imposing a deduction of 8% from the total payable to them for drugs and containers supplied and for professional services.

Medical Conference at Verona

Two Nobel laureates, Prof G Domagk and Prof E Moniz, are taking part in the International Medical Week which is being held at Verona from July 20 to 30. Other speakers will include Mr T Holmes Sellers, Mr C Brock, and Dr R P Liston (London), Prof H Olivecrona and Prof C Crafoord (Stockholm), Dr A Waksman (New Brunswick), and Dr D B Dill (Maryland). Further particulars may be had from Prof Luigi Barchi, Pescheria Vecchia, 6, Verona, Italy.

Medical Insurance Agency

The annual meeting of the Medical Insurance Agency was held in London on June 23. The report for 1949 disclosed a record amount of service to the profession (life insurance negotiated by the agency totalled about £2,976,000), a record total of rebates of premium, and a record profit available for medical charities. New covenants were entered upon with the Royal Medical Benevolent Fund, the Royal Medical Foundation of Epsom College, and the Benevolent Fund of the British Dental Association. Dr James Fenton was re-elected chairman, and Dr Henry Robinson hon. secretary, of the committee of management.

Reciprocal Health Service Arrangements with Jersey and Guernsey

A reciprocal health service agreement has been concluded between the Ministry of Health and the Department of Health for Scotland on the one hand and the States of Jersey and Guernsey on the other. Under the agreement, Channel Islanders may use the facilities of the National Health Service (other than those relating to mental health and mental deficiency) free of charge and arrangements will be made for the admission of Channel Islanders to hospitals in Great Britain where adequate hospital facilities do not exist in Jersey or Guernsey. As facilities are limited in the Channel Isles, and there is no free National Health Service there, a complete range of health service facilities cannot be offered to the large number of tourists from Great Britain who visit the Channel Islands each summer. Jersey will, therefore, provide free inpatient and outpatient hospital treatment, but no family doctor service. Guernsey will provide free inpatient hospital treatment and a family doctor service. No dental or ophthalmic treatment is to be provided by the States of either island. All free facilities provided by the States are for tourists from Great Britain only, and not for those who become resident in the islands. The States are to pay the Ministry of Health for certain accommodation in mental deficiency institutions in England and for some laboratory facilities.

Mental Health Conference

An informal conference to discuss better local co-ordination of home and hospital services in the sphere of mental health is to be held at the Town Hall, Salford, on July 14, at 2.30 P.M.

International Congress of Paediatrics

The sixth international congress of paediatrics is to be held at Zürich from July 24 to 28. The congress proper will be preceded and followed by two day courses of postgraduate lectures. The English speakers will include Prof J C Spence, Dr P L Mollison, Dr John Murray, Dr R R A. Coombs, Dr C E Dent, Dr Mildred Creak, Prof A St G Huggett, Dr Cicely Williams, Prof D R MacCallman, Prof Norman Capon, Dr Philip Evans, Dr C D S Agassiz, Dr Denis Hill, Prof J M Smellie, Prof Dorothy Russell, Prof Norman Dott, Dr F J Miller, Dr W R F Collins, Dr F O MacCallum, Mr T Holmes Sellers, Dr J H Hutchison, Dr Martin Bodian, Dr Bernard Schlesinger, and Prof A A Nonieroff.

The 1950 edition of the Register of Chiropodists has now been published. Medical practitioners may obtain a copy without charge on application to the registrar, Board of Registration of Medical Auxiliaries, Tavistock House North, Tavistock Square, London, W C 1.

In view of the very large demand for copies, the trustees of the Carnegie United Kingdom Trust have decided to put on sale to the public Dr Stott's report on *Delinquency and Human Nature*, which was originally printed for private circulation only (see *Lancet*, 1950, 1, 903). The charge, which is no more than a nominal one, and includes postage, is 5s in the sterling area or \$1 in America. Orders, with remittances, should be sent direct to the trust, Dunfermline, Fife, Scotland. The report is not available through trade channels.

CORRIGENDUM *Kernicterus and Prematurity*—In the penultimate paragraph of Dr Gerrard's letter last week (p 35), line 11 should read "but if this is so it would explain why hypoglycaemia."

SIGNIFICANCE OF THE DISCOVERY OF THE EFFECTS OF CORTISONE ON RHEUMATOID ARTHRITIS *

G W PICKERING

M.A., M.B. Camb., F.R.C.P.

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON,
PHYSICIAN TO ST MARY'S HOSPITAL

THE discovery by Hench and his colleagues, announced a year ago, that 'Cortisone,' or Compound E of Kendall, exerted a dramatic beneficial effect on both objective and subjective disturbances of rheumatoid arthritis, may be likened to Magellan's discovery of the straits that bear his name. For although the existence of a vast ocean beyond the Americas had been known since the conquistadores crossed the continent, its exploration had been delayed by the absence of any known inlet from the seas of the Old World. The discovery of the effect of cortisone, and later of the similar effect of adrenocorticotrophic hormone (ACTH), not only on rheumatoid arthritis but on a variety of diseases of hitherto unexplained pathology, seems to provide a means by which their pathology and pathogenesis will ultimately be solved. This is the great significance of the discovery. But there is another side which must be mentioned first.

EXPERIMENTAL APPROACH TO THERAPEUTICS

It has long been apparent that therapeutics should be an experimental science. There is only one basis for using a therapeutic agent—namely, that it acts beneficially in the particular disease in which it is used. Therapeutics treated in the traditional manner, as applied pharmacology, is a legacy of an age the therapeutic poverty of which is shown by the long lists of mixtures whose only virtue in many instances is their harmlessness to the recipient.

The use of the experimental approach to therapeutics has already revolutionised our conception of many diseases, particularly the anemias and the nutritional deficiencies. Hench's discovery of cortisone was not a flash in the pan; it was the fruit of a lifetime's use of the experimental method in the treatment of rheumatoid arthritis. For Hench applied this method to every treatment that has been suggested, with most of them the therapeutic effects were doubtful, although occasionally dramatic improvements were seen. The two most consistently beneficial agents were pregnancy and jaundice. One by one the possible substances that might be increased in these two conditions were tried, until eventually sufficient Compound E became available. This happened curiously as a side effect of war. It was suspected that adrenal steroids were being manufactured in Germany with the object of improving the efficiency of the Luftwaffe pilots, and their manufacture on a large scale was therefore started in the United States. When Compound E became available it was tried in rheumatoid arthritis with such care that its effects were clearly demonstrated in the first patient treated (Hench et al 1949).

My tribute to the work of Hench and his colleagues is all the more sincere because I failed in a similar quest myself. This story I will relate briefly.

I began with the idea that since the pathology of rheumatoid arthritis was quite unknown it might be discovered by chance observation based on any hypothesis, however absurd, and that the most likely field in which to make a chance discovery was in the field of therapeutics. In 1939, on published accounts, the most effective therapeutic agent in rheumatoid arthritis

seemed to be gold. I could not believe that gold was acting by restoring a deficiency of the metal, and it seemed possible that the effective agent might be an impurity in the gold preparations present in minute quantities.

Professor Dingle, then of the Imperial College, kindly made a spectrographic analysis of four gold compounds. This revealed many impurities, most of which were obviously of no significance, such as sodium and calcium. Professor Dingle was, however, impressed by the presence of barium, which he found in mother's milk. To get a further lead I took (in carefully cleaned glass syringes) the blood from three patients with rheumatoid arthritis, one of whom had been treated with gold, and three normal subjects of similar age and sex, I put them in specially cleaned and identical tubes and sent them to Professor Dingle. He found by spectrographic analysis that the metallic components of the two series were identical except for the presence in the rheumatoid arthritis patients' blood, of a gold line, slightly stronger lead and aluminium, and slightly weaker lithium and barium lines.

I therefore began treatment with barium chloride. My first case was a boy aged 17 whom I had had under observation for ten months with a severe widespread rheumatoid arthritis. He had not responded to gold and other treatment. I gave him barium chloride in half-grain doses by mouth three times a day for ten days, during the latter part of which he showed albuminuria and hypertension which disappeared when barium was stopped. His arthritis was dramatically relieved. He was discharged from hospital and returned to work and had remained well two years later when I last heard from him.

This seemed like the great therapeutic discovery of which I had dreamed, but unfortunately I have never been able to obtain albuminuria, hypertension, or a significant effect on rheumatoid arthritis with barium chloride in any subsequent case. In fact, before Hench's discovery, I had come to the conclusion that the effects of known therapeutic agents in rheumatoid arthritis were quite unpredictable, and it seemed to me that the changes I was witnessing were no more than the spontaneous remissions and relapses of a chronic disease.

I have related this fruitless experiment partly to draw attention to the fact that there is no disease as yet recognised in man that corresponds to the trace-element diseases so fully recognised and described in domestic animals and in plants by the Australian veterinary and agricultural research workers.

CAUSES OF DISEASE

To return to the problems of the pathogenesis of rheumatoid arthritis and the other so-called rheumatic diseases. I will not attempt here to define disease but will merely remind you that the state in which the animal finds itself at any time is determined by two prime factors—its inherited constitution and the effects of its environment, past and present. The common causes of disease thus include

- 1 Inborn and inherited abnormalities (e.g., hæmophilia)
- 2 The effects of excess of a chemical agent in the environment (poisoning e.g., lead poisoning)
- 3 The effects of a deficiency of a chemical substance (deficiency diseases e.g., beriberi)
- 4 Infection or infestation by viruses, bacteria, fungi, or animal parasites.
- 5 Physical trauma

It is to be noted that a possible additional category may exist in this system which is as yet unrepresented by any known disease, comprising diseases due to the absence or deficiency of microbes that normally live in or on their host and contribute to his welfare.

If we take up a textbook of medicine and we list the diseases that can be attributed to the above causes we find that there is an enormous residue in which the cause is not known. It seems possible that many of these diseases will prove to belong to the above categories, singly or in combination, but we must be alive to the possibility that there exists a group or groups of diseases

* A lecture given at St Stephen's Hospital, Fulham, introducing a postgraduate weekend course on rheumatic diseases.

the causation of which we do not comprehend, or comprehend but dimly. To this category belong the rheumatic diseases and other important maladies such as peptic ulcer and ulcerative colitis.

In the present century three hypotheses of disease have attempted to explain these maladies.

Focal Sepsis?

First came the hypothesis of focal sepsis. This supposed that a small localised infection could produce generalised disease, the remote manifestation being attributed to either bacterial dissemination, allergic tissue responses, or absorption from the focus of "toxins". In addition to the diseases above mentioned, the anæmias, nephritis, and many other conditions were attributed to this cause.

As a student I never understood the appeal of this hypothesis to my teachers. It had three gross defects.

- 1 As far as I knew it had never been shown, in a manner that would stand a critical analysis, that there was a significant association between the presence of a septic focus on the one hand and the disease in question on the other. I personally saw many patients with obvious septic foci but without these diseases, and many with these diseases but without obvious foci.
- 2 In many cases, there seemed to be no demonstrable effect on the course of the disease from removing the foci.
- 3 It was difficult to explain why (a) a variety of organisms should cause the same disease entity, and why (b) a single organism should cause a variety of disease entities.

I think the absence of any appeal in the hypothesis for a critically minded student, and its acceptance by his teacher who had been in practice for many years, was probably to be explained along the same lines as Lincoln's explanation of why North and South looked at the question of slavery in an entirely different light. As Lincoln said, "the South sees the question through a wad of two billion dollars."

Psychosomatic Origins?

The hypothesis of focal sepsis is now almost dead and buried. Its place has been usurped by the psychosomatic hypothesis which attributes disease to certain abnormal states of the mind. The rise of this hypothesis to dominance took place after the anæmias had begun to yield their secrets to the method of experimental therapeutics, but apart from this it has inherited much the same list of diseases, including rheumatic diseases, ulcerative colitis, and peptic ulcer. But, again, to a simple minded student the same objections arise as to the hypothesis of focal sepsis.

- 1 It has not been demonstrated that there is a significant association between the abnormal mental states and the diseases in question.
- 2 Psychotherapy seldom produces dramatic or repeatable effects in these diseases.
- 3 The hypothesis fails to account for (a) the variety of mental states causing the same disease entity, and (b) a single mental state being associated with a variety of disease entities.

The small amount of critically established fact on which these two hypotheses were based can probably be accounted for on the fact that the condition of any patient suffering from a chronic disease deteriorates when there is superadded infection or disturbance of the mind.

Diseases of Adaptation?

The last recruit to this series of general hypotheses is the theory of diseases of adaptation put forward by Hans Selye, of the University of Montreal. Selye has studied the resistance of experimental animals to a variety of stresses, such as severe infection, poisoning, intense muscular exercise, exposure to cold, solar or roentgen irradiation, nervous stress, and fasting and has described a series of systemic reactions of the body following continued exposure to these agents. These reactions he calls the general adaptation syndrome.

Among the most prominent effects are enlargement of the adrenal cortex with increased corticoid secretion, involution of the thymus and other lymphatic organs, gastro intestinal ulcer, metabolism changes, and variations in the resistance of the animals.

Selye (1946, 1949) divides the adaptation syndrome into three successive stages. The first, the alarm reaction, has two phases—the phase of shock in which the changes found represent the damaging effects of the agent, and the phase of counter shock in which the signs and symptoms of shock tend to be reversed, and in which the changes in size and function of the endocrine and lymph glands begin to show themselves. The second stage is the stage of resistance, which is essentially a prolongation of counter shock. In this stage resistance is increased to the particular agent to which the body has been exposed, but decreased to other types of stress. The third stage is that of exhaustion, in which the mechanism previously endowing the animal with resistance ceases to operate and the animal reverts to the stage of shock which is shortly succeeded by death.

Selye has produced evidence that many of the changes which are features of the adaptation syndrome are effected through the hypophysis, whose secretions affect the relevant tissues of the body and particularly the adrenal cortex. It is, above all, Selye thinks, the secretions of the adrenal cortex which produce changes on which resistance depends, and which are concerned in what he calls the diseases of adaptation.

The concept of the diseases of adaptation derives from the finding of certain lesions in the tissues of animals exposed to injurious agents, and in particular the lesions produced by injecting desoxycorticosterone into animals sensitised by high salt intake or nephrectomy. A list given by Selye (1949) of the diseases of adaptation is as follows.

DISEASES OF ADAPTATION DUE TO ENDOCRINE DISTURBANCES

- 1 *Hyperfunctional*
 - (a) Primary diseases of endocrines which participate in the general adaptation syndrome
 - 1 Cushing's disease (pituitary hyperfunction)
 - 2 Adrenal tumours with Cushing's syndrome (adrenal cortical hyperfunction)
 - 3 Chromaffinomas (adrenal medullary hyperfunction)
 - 4 Coarctation of the renal artery and other primary diseases of the kidney conducive to hypertension (renal hyperfunction (hormonal))
 - (b) Secondary diseases due to excessive (or abnormal) response of endocrines to stress
 - 1 Some types of hypertension
 - 2 Periarthritis nodosa (also arteriosclerosis and other vascular lesions ?)
 - 3 Nephrosclerosis
 - 4 Some types of nephritis (?)
 - 5 Rheumatic disease (?)
 - 6 Waterhouse-Friedrichsen syndrome
 - 7 Eclampsia (?)
 - 8 Accidental thymus involution
 - 9 Some types of tonsillitis (?)
 - 10 Some types of appendicitis (?)
 - 11 Gouty arthritis (?)
 - 12 Some types of diabetes
- 2 *Hypofunctional*
 - (a) Primary diseases of endocrine which participate in the general adaptation syndrome
 - 1 Simmonds's disease (pituitary hypofunction)
 - 2 Addison's disease ("status thymicolymphaticus" (?) adrenal-cortical hypofunction)
 - (b) Secondary diseases due to insufficient response of endocrine to stress
 - 1 Secondary shock (relative hypocorticism (?))
 - 2 Acute gastro intestinal erosions ("Curling's ulcer")

Selye's conception of the causation of these diseases is as I understand it, approximately this. An individual is subjected to a stress, such as severe infection, poisoning, intense muscular exercise, exposure to cold, a severe mental strain, or fasting. The adaptation syndrome, with all its complex endocrine changes, is brought into play, but one of the secretions is of abnormal magnitude or perhaps the structures on which it acts are abnormally sensitive, and the corresponding set of pathological changes, with their clinical counterpart, ensues.

This hypothesis is suspiciously like its predecessor, the hypotheses of focal sepsis and of the psychosomatic

origin of organic disease, and my own first reaction to it was unfavourable. I thought it tried to explain too much on too little evidence, and that the same kinds of criticism which could be levelled against the two other theories were applicable equally to it. For instance there are many examples of these diseases in which it would be difficult adequately to define the initiating stress, and many examples in which the stress occurred without the disease. And I still find it hard to believe that diseases having such different incidence, different pathologies and different courses, as the diseases Selye has listed, can arise from one and the same mechanism.

It is worth noting, however, that Selye's hypothesis is more solidly backed by experimental evidence than its predecessors. Moreover the great weakness of the hypothesis of focal sepsis and of the psychosomatic hypothesis is the relative inefficacy of therapeutic measures which it prompted. Hench's discovery, which incidentally was made quite independently of this hypothesis, showing that one of the secretions of the adrenal gland would abolish many features of the pathological changes of rheumatoid arthritis, at once made the new hypothesis more plausible—especially when it was found that cortisone effected dramatic improvement in other diseases and that similar effects were produced by the adrenocorticotrophic hormone of the pituitary gland. The first publication of the effects of cortisone is now only a year old, and the information about these diseases responding to A.C.T.H. is notably incomplete. Much of the evidence remains unpublished, and any list will probably require revision both by elimination and addition when more information is available. On present information, the following conditions respond

Rheumatic fever	Dermatomyositis
Rheumatoid arthritis	Lymphatic leukaemia
Psoriasis	Ulcerative colitis
Lupus erythematosus	Bronchial asthma
Polyarteritis nodosa	Urticaria

This is not the time nor the place to enter into a detailed discussion of the validity of Selye's hypothesis. It will serve its purpose by stimulating inquiry, and it will stand or fall as a result of the facts revealed by observation and experiment. One caution is, however, very necessary. The history of medicine shows how great is the tendency for a tentative and imperfectly documented hypothesis to assume the guise of a so-called fundamental principle. This tendency is particularly great in the diseases here considered, whose causation has hitherto been shrouded in impenetrable darkness, now at last dimly lit.

HOW DOES CORTISONE ACT?

With this background we may turn to consider more closely how it is that these substances improve the diseases listed.

On Selye's hypothesis, the diseases might be produced by excess of the mineralocorticoid secretion of the adrenal not balanced by a corresponding secretion of glucocorticoid. Administration of cortisone would correct this disturbed equilibrium directly, and A.C.T.H. would correct it indirectly. The difficulty in accepting this hypothesis is this. Administration of deoxycortone in large doses to man is known to produce oedema and hypertension, the hypertension being prevented by simultaneous dosage with cortisone. But overdosage with deoxycortone in man, has, as far as I am aware, never produced any of the maladies in my second list. Nor are the classical signs of deoxycortone overdosage—oedema and hypertension—found as a rule in these diseases. Unless, therefore, the mineralocorticoid in question is one with properties very unlike deoxycortone, it cannot be accepted that overproduction of these substances produces these diseases.

The diseases are obviously not due to a total deficiency of suprarenal secretion, since they are never or seldom

seen in association with Addison's disease. It is possible that while the secretion of mineralocorticoids is normal, the secretion of the glucocorticoids is diminished. This would explain the action of cortisone producing a remission in these diseases during its administration. The recent observations of Sprague and others, including Hench and Kendall, are relevant to this theme (Sprague et al 1950). They report the effects of cortisone on 26 patients treated with 74 to 200 mg (of acetate) per day for long periods. Many of these patients developed rounding of the facial contours, and one patient who received cortisone for 187 days developed acne and hirsutism. Other features of Cushing's disease were keratosis pilaris, muscular weakness, oedema, amenorrhoea, cutaneous striae, mental depression, impairment of carbohydrate tolerance, negative nitrogen balance, increased excretion of corticosteroids in the urine, and alkalosis with diminished blood chloride and potassium. Significant hypertension was observed in only 1 case. The doses used produced remissions in rheumatoid arthritis and rheumatic fever, disseminated lupus erythematosus, psoriasis, and psoriatic arthritis, but the rheumatoid changes returned after the treatment was withdrawn.

What we do not yet know is whether the smallest doses necessary to produce a remission in these diseases will if continued over many months, produce the symptoms of Cushing's disease. If so, then it seems unlikely that a simple deficiency of glucocorticoid secretion is a factor in pathogenesis. Support to this idea is given by the work of Thorn and Bawles (1949) who have found that 10–20 mg cortisone per day is sufficient to maintain the health of a patient with complete adrenal insufficiency, while 100 mg per day is necessary to produce significant changes in rheumatic diseases. They state that "effective therapy is only attained when the level of the hormone is clearly increased either from subnormal to above normal or from normal to above normal." Clearly, however, the problem of the amounts actually secreted must await a satisfactory method of assay.

A.C.T.H.

The conditions benefited by A.C.T.H. and cortisone have certain features in common. Some of them, such as rheumatoid arthritis, polyarteritis nodosa, scleroderma, and lupus erythematosus, are diseases that are said to affect particularly the structure of collagen, and are sometimes grouped as "collagenoses." Others, such as urticaria and asthma, are known to be associated with a hyper sensitivity state, in which the tissue reactions to specific chemical substances are abnormally intense. Each of these leads is worth following.

These hormones may profoundly affect the tissue cells. A.C.T.H. decreases conspicuously the number of circulating eosinophils and diminishes the amount of lymphoid tissue. Thorn and his colleagues have shown that the disappearance of eosinophils from the blood after A.C.T.H. depends on the presence of the adrenals and is therefore mediated by a substance secreted by the adrenals. Sprague and his colleagues find that prolonged administration of cortisone produced a small but significant increase in the total number of leucocytes but no significant change in eosinophils or lymphocytes, while A.C.T.H. led to complete or almost complete disappearance of eosinophils. Thus these changes in white blood-cells would seem to depend on the secretion by the cortex of a substance other than cortisone, possibly Compound F. More significant are their effects on tissue reactions. It is said that wounds show diminished power of healing and abscesses reduced formation of granulation tissue in patients (or animals) to which the hormones are being administered. It is evident then that these hormones have a very profound effect on the tissue reactions of the body apart from the diseases which they relieve.

On what exactly this effect depends is still unknown, but it seems to me that here may lie the answer to the riddle of these diseases

Bordley et al (1949) have reported dramatic improvement with A.C.T.H., given in doses of 30-100 mg daily for 11-21 days, in such maladies as severe exfoliative dermatitis, giant urticaria due to penicillin, and bronchial asthma "In two patients there was complete obstruction of the nose by polyps. These began to shrink on the third day of treatment and by the end of therapy had completely vanished in one, and almost completely in the other." Long and Miles (1950) have investigated the effects of thyroxine and of cortisone on the tuberculin reaction in the guinea-pig sensitised by B.C.G. They have shown that thyroxine enhances the sensitivity to tuberculin, while cortisone reduces it. After stopping cortisone, the sensitivity is increased for a while beyond the normal, just as the rheumatoid changes may be increased after withdrawal of the drug. Thus there seems to be clear evidence that the cortical secretions affect certain kinds of tissue hypersensitivity, but again it is unknown how this is brought about.

SIGNIFICANCE OF THE DISCOVERY

Sprague and his colleagues concluded that it was not yet possible to account for the action of cortisone or A.C.T.H. in disease by any effect of these substances as yet fully understood, and in spite of a spate of recent publications that position remains unchanged. It is evident that cortisone and A.C.T.H. modify tissue responses, and that many of the diseases listed show a peculiar tissue response that is annulled by these agents. What is the essential peculiarity of this tissue response and how it arises are questions that we cannot yet answer. What is clear is that in these compounds we have new tools with which to attack some of the more obscure reactions of the body, and that the result of this attack may be the recognition of a new category in the causation of disease. That, it seems to me, is the significance of this great discovery. And while we must recognise that behind this discovery is a vast effort by chemists, biochemists, and experimental biologists, I would emphasise that the discovery itself was in the field of experimental therapeutics.

Finally a word about practical therapeutics. Although it is too early to form a final opinion, it appears probable that the effects of cortisone or A.C.T.H. are curative in certain self-limited diseases such as rheumatic fever. But in chronic diseases, such as rheumatoid arthritis, the signs and symptoms recur after stopping treatment. Moreover it seems, though it is by no means certain, that the minimum dose of cortisone or A.C.T.H. necessary to produce a remission in these diseases also produces undesirable side effects such as the manifestations of Cushing's syndrome already mentioned. Another adrenal constituent or a close chemical relative may prove to be more effective than cortisone and to act in doses that have not these adverse consequences. New knowledge of the disease processes concerned may produce completely new remedies. It is to be hoped therefore that cortisone and A.C.T.H. may ultimately be displaced as therapeutic agents by something whose effects are more narrowly confined to the fundamental disturbance in these diseases.

INVESTIGATION OF THYROID FUNCTION AND DISEASE WITH RADIOACTIVE IODINE *

E. E. POCHIN

M.D. Camb., F.R.C.P.

DIRECTOR, DEPARTMENT OF CLINICAL RESEARCH, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

(Concluded from p. 46)

Second Phase of the Iodine Cycle Retention in the Thyroid

The thyroid concentration of administered radio iodide is largely complete within 2-3 days in normal subjects and often within 12 hours in Graves's disease. The radio-iodine so concentrated is at first retained in the thyroid before circulating as thyroxine and finally returning from the tissues to re-enter the iodine cycle (fig. 8).

The amount of radio iodine retained within the thyroid can be accurately followed by measuring the counting rate opposite the neck during the first weeks after the dose. In normal subjects, and in most patients with untreated Graves's disease, the total thyroid content

Fig. 8—Radio-iodine cycle indicating approximate periods of stay of iodine at different stages of the cycle

of radio iodine falls by only a small percentage of its value each day, the normal average fall representing a daily loss of 0.6% of the dose. The fall is usually more rapid in Graves's disease, averaging 6% per day.

These values clearly measure the over all loss by the gland—namely, the difference between its output and any intake that may be continuing. To determine the daily output, therefore, we must first know, and allow for, the intake. This cannot be determined directly, but can be estimated if certain assumptions are justified. We have seen that the original dose of radio iodide was shared between thyroid and kidney in the ratio of their plasma clearance rates, the thyroid uptake rate at any time being in this proportion to the renal excretion rate. If at later periods the thyroid and kidneys are again taking up iodine as it returns from the tissues in the form of iodide, the same relationship should hold, and the thyroid uptake rate should be calculable from the urinary excretion rate, if the proportion between the

* The Oliver Sharpey lectures delivered at the Royal College of Physicians of London on March 14 and 16. Based on work undertaken for the Medical Research Council, in conjunction with B. D. CORBETT B.A., the late E. A. G. GOLDIE, M.B., A. J. HONOUR and N. B. MANT B.M.

clearance rates has been determined. This assumption would not hold if radioiodine, while circulating in organic combination, were also taken up directly by thyroid or kidneys in appreciable amounts, but we have obtained some evidence that this is not an important source of error. When synthetic crystalline thyroxine, labelled with radioactive iodine atoms, is given intravenously to man, we have found radioiodine only to appear slowly either in the thyroid or in the urine (Myant and Pochin 1950). In both there is some concentration of radioiodine, which is probably due largely to liberated iodide being concentrated in the usual way, as the rates of thyroid and urinary radioiodine accumulation are in about the ratio as normally observed after radioiodide. Further work is needed on the human thyroid uptake and renal output of the iodotyrosines and other organic iodine compounds, but it appears that the thyroid uptake-rate may be calculated from the renal excretion rate with sufficient accuracy for the present purpose.

In normal subjects the initial rapid excretion of radioiodine is over within the first 3 days. Thereafter, urinary excretion continues at a low but roughly constant rate, which averages 0.4% of the dose per day. Since the normal thyroid clearance is about three quarters of the renal clearance, the continuing thyroid uptake should at this period be about 0.3% per day, on the assumption made. Meanwhile the overall loss from the thyroid averages 0.6% of the dose per day, so that the daily output must be 0.9% of the dose. In Graves's disease the thyroid, after an initial large and rapid uptake, decreases in radioiodine content by 6% of the dose per day despite a high continuing daily intake of 8%, indicating a daily output by the gland of 14% of the dose.

The mean stay of a radioiodine atom in the gland may be calculated from knowledge of the proportion of such atoms which are discharged each day. In twelve patients with Graves's disease an average of 20% of the gland's radioiodine content was discharged daily, which implies a mean length of stay of about 5 days, the value ranging in different cases from 1 to 17 days. In eight subjects without thyroid disease, an average of 3% of the gland's radioiodine was discharged daily. The normal mean stay is thus considerably greater than in Graves's disease and, if the proportion of radioiodide atoms discharged daily remained constant, would be about 5 weeks. Further work is needed to justify the calculation of thyroid intake from urinary output, but it is clear that the time spent by iodine atoms in each passage through the thyroid gland in Graves's disease is greatly reduced and commonly to one tenth of its normal value. The acceleration of thyroid iodine turnover may thus be as great as the acceleration of iodide uptake.

Third Phase of the Iodine Cycle: Circulation as Thyroxine

In the third phase of the cycle, iodine is discharged from the thyroid in organic combination and circulates in the blood-stream, probably as thyroxine in loose combination with plasma albumin. We may examine the kinetics of this phase by following the plasma radioactivity and may form some estimate thereby of the length of time spent by iodine in the plasma as thyroxine. It is useful to consider first the findings in Graves's disease. In these patients, the plasma radioactivity, which falls rapidly in the first few hours while the dose, in the form of iodide, is being removed from the blood stream, begins to rise again within a day as radioactive thyroxine begins to be liberated. Such radiothyroxine has been detected within 3 hours of the dose in one case, and repeatedly within 7 hours in Graves's disease. Correspondingly, the total plasma radioactivity passes its minimum and starts to rise by 9 hours.

In its subsequent course, the plasma radioactivity probably measures radiothyroxine content to a close approximation, with iodide contributing only slightly to the total radioactivity. By the method used, it has not been possible to detect and separate countable amounts of radioiodide in the presence of radiothyroxine at this stage. The maximum possible content of free radioiodide can, however, be estimated from a knowledge of the renal excretion rate, and of the renal clearance for iodide. On this basis, it is estimated that radioiodide has been responsible for under 3% of the plasma radioactivity in thyrotoxic subjects, subsequent to one day from the dose. The plasma radioactivity curve therefore probably represents the course of radiothyroxine accumulation in the plasma. The average value in a group of cases of Graves's disease rises towards a maximum concentration which is reached within a few days and is then maintained for many days (Myant and Pochin 1949). This form of plasma concentration curve is readily interpreted. It is of a type to be expected on mathematical grounds if radiothyroxine enters the circulation at a constant rate, but leaves it at a rate proportional to its concentration therein. The first condition holds in these cases, since the rate of radioiodine output from the thyroid is about constant over the first few days, so that radiothyroxine is probably entering the circulation at a steady rate. The second condition should also hold, since radiothyroxine molecules are indistinguishable chemically from the much greater and relatively constant number of circulating normal thyroxine molecules. The number of radiothyroxine molecules which happen to be metabolised each day should thus depend on the proportion present—that is, on the concentration of these radiothyroxine molecules in the plasma. Under these conditions we should expect the plasma radiothyroxine concentration to rise exponentially towards a plateau value, and this is observed.

To express this conclusion algebraically, if the constant rate of output is A , and if a constant fraction f of the radiothyroxine molecules is removed each day, then the plasma concentration x should vary with time t so that

$$\frac{dx}{dt} = \frac{A}{V} - fx$$

whence

$$x = \frac{A}{Vf} (1 - e^{-ft})$$

where V is the body thyroxine space. The plasma concentration should approach a limiting concentration of value $\frac{A}{Vf}$ from which A may be estimated, as discussed later. It should approach it exponentially with a time-constant determined

Fig 9—Plasma radio-iodine concentration in patients with Graves's disease in the weeks following a dose

by the value of f , and the mean life of the circulating thyroxine molecule should be equal to $1/f$

This interpretation is also consistent with the data from certain thyrotoxic patients in whom the thyroid output is initially much more rapid but decreases substantially during the first few days after the dose (fig 9). In these patients, it is found that the plasma radio iodine also rises to a concentration which is initially high but falls progressively after a maximum value at about the 5th day, and this type of curve would be expected in view of the decreasing rate of thyroid output during this period. In both groups of cases, it is assumed that the diffusion of thyroxine through the body tissues is rapid compared with the process of its removal, and some evidence that this is so has been obtained by giving synthetic crystalline radiothyroxine intravenously when the final distribution through the body is approached within a few hours of the dose (Myant and Pochin 1950).

It will be observed that, although the maximum plasma concentration varies considerably in different patients, this maximum value is attained in roughly equal times, the curves usually rising to half their greatest height by between 1 and 2 days (see table). If the interpretation of the form of these curves is correct, the mean lifetime of radiothyroxine in the circulation may be estimated from them. For, as is shown above, the time in which the plasma radiothyroxine reaches half its limiting concentration will be equal to that in which half of any group of radiothyroxine molecules disappear from the circulation or body fluids. The average half time in twelve thyrotoxic patients has corresponded to a mean lifetime of 2 days for a circulating thyroxine molecule in Graves's disease. In normal subjects the plasma radio iodine rises to a lower limiting concentration which is probably reached in about the same time as in Graves's disease or perhaps somewhat later, but the speed of this phase of the iodine cycle appears to be much less affected than are those of the thyroid uptake and discharge.

It may be noted here that the "mean lifetime" strictly refers to the period until either the thyroxine molecule is removed from plasma and the fluids in equilibrium with it, or the radio iodine atom is removed from the molecule. Since the biosynthesis of thyroxine after tracer doses of radio iodine occurs in the thyroid in the presence of large concentra-

tions of normal iodide, it is highly unlikely that any thyroxine molecule will contain more than one radio iodine atom. We may therefore be studying the survival of iodine in thyroxine molecules of four types, labelled in the 3, 5, 3', and 5' positions. If the stability of iodine depends on the aromatic ring to which it is attached, the radiothyroxine of which the mean lifetime is studied may be a mixture in equal parts of two types of unequal lifetime. In this respect, radiothyroxine synthesised artificially by radio iodination of 3,5-diiodothyronine using carrier free radio iodide may differ from biosynthesised radiothyroxine in uniformity and in survival as such within the body.

In myxoedema, as in Graves's disease under thorough treatment, no later rise in the plasma radio iodine has been detected in the week following the dose.

We may hope to carry the analysis of thyroxine metabolism a little further, although the conclusions must at present be tentative.

Suppose that a patient achieves a plasma concentration of thyroxine equivalent to 2% of the dose per litre. Suppose also that we accept a diffusion space of 15 litres for this thyroxine, based on that for crystalline radiothyroxine injected intravenously. This would imply that 30% of the dose is present as thyroxine. If now we estimate the lifetime of this circulating thyroxine, we may calculate the rate at which thyroxine must be entering and leaving the circulation to maintain this level. If, for example, the mean lifetime is one day, then 30% of the dose must leave the thyroid each day as thyroxine.

We thus obtain the gland's daily output of radiothyroxine. But we already have an estimate of its total daily output of radio iodine in all forms. We may therefore hope to establish what proportion of its discharged iodine is in the form of thyroxine. It will be of interest to find out whether the same proportion of iodine is put out as thyroxine in Graves's disease as in normal conditions, or to investigate the biochemical possibility that one molecule of diiodotyrosine is liberated for every thyroxine molecule discharged from the thyroid. At present, however, the diffusion space for normal body thyroxine cannot be stated with certainty. It is found that crystalline thyroxine is distributed through about 15 litres in normal subjects. On the other hand, if the plasma of a patient under radio iodine treatment for thyrotoxicosis is injected intravenously in man, the radio iodine compounds present may remain concentrated in a few litres only of the recipient's circulation, and the cause of this discrepancy is not yet clear. Calculations on a small group of thyrotoxic subjects have shown, however, that if the 15 litre space is assumed for thyroxine as normally discharged into the circulation by the thyroid, there is an approximate equivalence between the thyroid output of radio iodine and the output in the form of thyroxine. This subject requires considerably fuller and closer investigation, but the use of radio iodine appears to be capable of giving an answer to the question.

The Complete Iodine Cycle

We have now traced the circulation of iodine through three phases of its body cycle, and obtained some estimate of its normal length of stay in each phase.

ig S)—namely, for a matter of hours as iodide in the blood (say, 6–8 hours in normals and 1–2 hours in Graves's disease), for weeks in the thyroid (perhaps for weeks in normals and 1 week in Graves's disease), and probably for a few days only as thyroxine in the blood.

If thyroxine is then broken down in the tissues and the radio iodine released again as iodine into the plasma, it will either be excreted in the urine or be taken up by the thyroid to re-enter the same metabolic cycle. The importance of this recirculation of iodine can be seen in some patients with Graves's disease in whom the whole iodine cycle is rapid and, because the thyroid clearance is high relative to the renal clearance, most of the iodide returning to the plasma from the tissues re-enters the cycle. In one such patient radio iodine was found to be re-entering and flowing through the thyroid in amounts

exceeding the original dose each day, so that some iodine atoms must have completed the whole body cycle in less than a day. A rough estimate can be made of the average time of a complete circuit of the body.

Taking a very simplified argument suppose that a dose of radio iodine is given

Fig. 11—Distribution of radio-iodine at one, two and six days after a dose in a patient with Graves's disease showing concentration in liver area appearing on second day.

intravenously to a subject in whom the thyroid and renal clearances happen to be equal. The radio iodine will be shared so that 50% is excreted in the urine and 50% is concentrated in the thyroid. If the 50% from the thyroid now completes its circuit of the body once and reappears in the plasma as free iodide, it should again be shared equally between thyroid and kidney, 25% now going to each. The time at which this circuit is completed should thus be marked by the excretion of a further 25% of the dose in the urine. The next cycle is marked by the excretion of half the remainder and so on repeatedly, the duration of each cycle therefore being established.

In effect, we are comparing the total amount of radio iodine left in the body with the amount that flows out of the tissues each day, and so estimating the number of days that must elapse before it all has passed once round the cycle. It may thus be possible to estimate a time for the total circuit by comparing the urinary excretion-rate with the amount of radio iodine remaining in the body, provided the thyroid and renal clearances are known.

This is clearly an oversimplified presentation. It is likely, for example, that some iodine atoms will have started a second circuit before all have finished the first. It is unknown whether iodine is liberated from the tissues only in the form of iodide. Finally, it is uncertain—and perhaps on biochemical grounds unlikely—that iodine atoms are liberated from the thyroid only as thyroxine. If some are discharged as duodotyroline these may be liberated as iodide much sooner than those discharged as thyroxine and the estimated time of

Fig. 12—Carcinoma involving left lobe of thyroid. Counting rates at different positions on the neck with contours interpolated at 250 counts per minute intervals.

circuit would be intermediate between that for thyroxine and that for duodotyroline. These points must be the subject of further work. It can, however, be stated that the total time of circuit calculated on these assumptions is in rough agreement with the sum of the estimated times of stay in thyroid and in plasma as iodide and thyroxine, which suggests that any further time of stay in tissues may be short.

If therefore we summarise our information on the circulation of iodine, the normal cycle appears to be as follows. Intravenously injected iodide distributes

Fig. 13—Relation between contours of radio-iodine activity (dotted lines) and structures palpable in neck (continuous lines). Case as in Fig. 12.

through the equivalent of 20 litres or one third of the body-weight in the course of 2 hours, entering saliva and gastric juice in high concentration and entering red cells rapidly to a concentration about two thirds that in plasma. Meanwhile, however, the thyroid and kidneys are removing about 20% and 3% respectively of the iodide in the blood passing through them, so that the thyroid clears an average of 25 ml and the kidneys 32 ml, of plasma of its content of iodide per minute. The iodide so concentrated in the thyroid gland remains there for a matter of weeks, passing thence into the circulation, where it remains as thyroxine probably for several days before being removed by the tissues. On its liberation as iodide into the circulation, it has a 40% chance of escaping removal by the kidney and repeating the cycle.

In typical Graves's disease the uptake of iodide is accelerated about tenfold, and the stay in the thyroid may be reduced to one of a few days only. The stay in the plasma as thyroxine averages 2 days, and 90% of the iodide released from the tissues is likely to re enter the cycle.

Now it is clear that, in a normal subject, a high dietary iodine intake will not in general cause an increase in thyroxine metabolism. It is therefore of physiological interest to find at which of the many stages of the iodine cycle the necessary control of thyroxine synthesis is exerted. In the presence of a high dietary iodide is absorption decreased, or the thyroid clearance of iodide reduced, or the renal clearance augmented? Is the discharge from the thyroid delayed or reduced in rate, or does thyroxine represent a smaller proportion than usual of the discharged iodine? Or is thyroxine more slowly removed from the blood stream and utilised in the tissues? Some evidence on this problem is accumulating, notably from observations by Stanley (1949) and by Keating and Albert (1949) on the maximum rate at which the human thyroid can take up iodide. When the speed of each step can be separately assessed, however, it should be possible to estimate at which stages control is exerted physiologically.

This same type of analysis may also be of interest if we can identify which stages are influenced, and by

Fig 14—Contours indicating low activity (maximum 750 counts per minute) over carcinomatous right lobe and high counts (maximum 3250 counts per minute) over normal left lobe.

Fig 15—Contours grouped round position of normal thyroid tissue: uninfluenced by presence of carcinomatous mass in right lobe.

how much, in Graves's disease. It should then be possible to examine whether the same stages are affected in the same proportion, for example, by the thyrotropic hormone of the pituitary. If it were found that several steps in the iodine cycle were independent and were increased in Graves's disease, and that the appropriate dose of pituitary hormone increased all the same steps in the same ratios, this would give some presumptive evidence that the pituitary might be responsible for the changes observed in this condition. If, on the other hand, the pituitary were found to produce some but not all of the changes, or to influence different steps in proportions different from those by which they are affected in Graves's disease, this could be taken as evidence that the pituitary alone was not responsible for all the changes observed. And it is not too much to hope that a detailed analysis of the iodine cycle may throw useful light on the causation of this elusive disease.

Localisation of Radio-Iodine

Hitherto we have discussed mainly the circulation of radio iodine through the body at various times after its administration. As is well known, however, its distribution in different parts of the body can also be directly examined by external counting methods, which may yield information of value in both physiological and clinical work. The general distribution of radio iodine in the neck and trunk, for example, may be studied by making a series of measurements with a counter near the anterior midline of the body but at different distances down the midline. The distribution throughout the body may then be represented graphically by plotting each counting rate so observed against the corresponding distance from, for example, the cricoid cartilage. Such a "profile" of iodine distribution is given in fig 10 which depicts findings one day after an oral dose in a normal subject, with the counter at 10 cm from the anterior midline of the body and receiving radiation through a vertical angle of 90°. Localisation by this method, although sensitive, is inexact, and the effect of the thyroid is obvious at many centimetres from its position in the neck. The rise in counting rate over the lower abdomen is commonly ascribed to concentration of radio iodine in urine within the bladder. The smaller rise shown at the umbilical level is probably due to a similar renal concentration.

In normal subjects the distribution during the ensuing week shows only a high peak opposite the thyroid, falling to low levels over the trunk without evidence of other areas of high concentration. In several thyrotoxic subjects, however, in whom the distribution has been

examined, considerable local concentration develops in the region of the liver (fig 11) by the second or third day, as the plasma thyroxine reaches its highest values, and this peak is conspicuous in cases with high plasma thyroxine concentration. Its maximum is at about the level of the ensiform cartilage and is greater to the right than to the left of the midline, and the data obtained appear to be consistent with the local concentration of thyroxine in the liver which has been postulated on other evidence derived from animal experiment (Gross and Leblond 1947). The maximum counting rate observed in this region is only a small percentage of that opposite the thyroid (fig 11), and is too low to allow the limits of the region to be accurately mapped by highly shielded directional counters. In one case it has been shown by cholecystography that the area of high counts does not correspond with the position of the gall bladder. We have observed a similar distribution in the hepatic region after the intravenous administration of synthetic radioactive thyroxine (Myant and Pochin 1950).

Another application of this relatively simple method of examining the body iodine distribution will be illustrated below in a patient with thyroid carcinoma. In most cases of clinical importance, however, it is desirable to localise iodine-concentrating tissue with greater precision. Counters used for this purpose are shielded with lead so that they respond only, or chiefly, to radio iodine below the skin at the site of measurement, the lead excluding radiations except from a narrow pencil of tissue near the axis of the counter. Such shielding can be designed to give accurate localisation, although at the expense of sensitivity. A series of readings can be obtained for example, at different points in the neck, indicating the distribution of radio iodine below the skin at these points. The counting rates observed are marked in fig 12 at the corresponding points on the neck of a patient with left sided thyroid carcinoma. This forms a chart of the distribution of radio iodine in the neck, which is more readily interpreted if contours are interpolated between the sites of measurement, corresponding to zones of equal radio iodine concentration. The position of such contours may then be compared with that of the structures locally palpable (fig 13). In this case, a hard and evidently carcinomatous

Fig 16—Contours indicating radio-iodine concentration in neck and over sites of lung metastases in chest.

mass had developed first and mainly in the left lobe of the thyroid with left sided pain. As is shown in fig 13, most at least of the iodine concentrating power of the affected lobe had been destroyed, that of the left lobe being preserved. This is unfortunately the commoner type of thyroid neoplasm, in which the carcinomatous tissue is too anaplastic to have preserved the capacity of concentrating iodine, at least in a degree which would make immediate treatment with radio iodine valuable. Cases of this type are illustrated in figs 14 and 15. In the former, a hard carcinomatous mass involved the right lobe, which was shown by this method to take up iodine only weakly, as compared with the active, and presumably more normal, left lobe. In fig 15, the pattern of radio iodine distribution is clearly uninfluenced by the presence of the carcinomatous mass in the right lobe, over which the contours are not deviated. In some of these, and in several other cases of thyroid carcinoma, metastases remote from the thyroid were examined by the same method and not found to take up detectable amounts of radio iodine. In a small proportion of cases of thyroid carcinoma, however, particu-

Fig 17A

Fig 17B

Fig 17—Comparison between position of lung metastases and counting-rate contours (dotted lines).

Fig 18—Response of body weight, basal metabolic rate, and heart rhythm to therapeutic doses of radio iodine in case of functioning thyroid carcinoma

larly those of slow growth and adenocarcinomatous structure, the tumour retains the iodine concentrating power of the original thyroid tissue. In these cases, radio iodine can be immediately used in therapy, even though generalised carcinomatosis has developed, since if all metastases throughout the body concentrate iodine, they will concentrate radio iodine and so can be selectively irradiated by the beta radiations from a large dose of this material.

A patient of this type had had a partial thyroidectomy for thyrotoxicosis in 1942 and was found to have a highly differentiated thyroid neoplasm with multiple secondaries in the lungs. After operation, her thyrotoxicosis recurred and her metastases slowly grew, and it became clear that she had the rare type of thyroid carcinoma in which the mere mass of functioning thyroid like tissue was sufficient to produce a clinical state of thyrotoxicosis. In May, 1949, she was weak, wasted, and severely dyspnoeic, her body weight being 6 st 1 lb, and she had cardiac enlargement, auricular fibrillation, and a basal metabolic rate raised by 69%. Multiple nodules, which proved to be carcinomatous, had recurred in the scar.

Of a tracer dose of radio iodine about one sixth was concentrated in the neck, one quarter was excreted, and over a half was accumulated in the lung area, the contours (fig 16) indicating selective concentration in the neck and in those

areas where metastases were known to be present. Examined in more detail (fig 17) and with directional counts over the back of the chest, the areas of high contours of radioactivity corresponded closely with the areas containing many of the large metastases shown radiologically.

This patient was therefore given radio iodine in therapeutic dosage—that is, in amounts over one thousand times as large as those ordinarily used for tracer investigation. The metabolic rate fell (fig 18), the heart reverted to normal rhythm in 6 weeks, and her body weight started to rise rapidly within 10 days of the first dose, and increased by 3 st to its previous normal value within 6 months. The thyroid and tumour tissue had received a total of about 15,000 röntgens, and the total amounts of radiation received by the body amounted to 3 and 7 megagramme röntgens which produced no clear symptoms of radiation sickness, but depressed the blood lymphocyte count moderately after each dose. The response of the lung metastases is shown in fig 19, and measurements indicate that the metastases shrank to one fifth of their previous volume. Further evidence of this destructive effect of the radio iodine radiation

Fig 20—Profile of body radio-iodine distribution before treatment, with concentration in lung and thyroid areas

on the lung metastases was obtained from the "profile" diagram of body iodine distribution, that before treatment showing (fig 20) high peaks of concentration opposite the thyroid and also opposite the lung fields in which metastases were present. After radio iodine therapy, further "profiles" were obtained 3 and 7 months later (fig 21). The radio iodine appeared in this case to have had a greater effect on the secondary neoplastic tissue in the lungs than on the normal thyroid or perhaps the primary neoplasm in the neck, so that the peak opposite the lungs was greatly reduced. Biopsy.

(A) (B)
Fig 19—Comparison between lung metastases (A) before and (B) after radio-iodine treatment.

Fig 21— Profiles of radio-iodine distribution before (May) and after (October and February) treatment which largely abolished concentrating metastases in lungs

however, showed persisting carcinoma cells in a neck nodule, and local counting over the chest revealed that lung metastases were still present and concentrated iodine. All identified iodine-concentrating tissue in the neck was therefore removed surgically, to confine the effect of further radio iodine doses to the lung metastases without competition by actively concentrating tissue in the neck.

Such treatment, even though at present palliative rather than curative, is clearly valuable for thyroid carcinoma which concentrate iodine, and several cases (Seidlin et al 1949) have been maintained in full health for over 5 years by this means.

It is evidently important that the iodine concentrating capacity of thyroid carcinomata should be investigated wherever possible. This will be possible if there are metastases remote from the gland, over which the counting-rate can be measured without interference by adjacent thyroid tissue. It will also be possible after total resection of the thyroid gland, and this operation, if practicable, is in any case a desirable preliminary to radio iodine therapy. In cases with local extension only in the neck, it will rarely be practicable to distinguish radio iodine uptake in tumour tissue from that in adjacent or underlying thyroid tissue. At best it may be shown that radio iodine is not taken up strongly, but weak uptake can never be excluded, nor the possibility of improved uptake after thyroidectomy. The choice of treatment for such patients is difficult and they form the majority of cases of thyroid carcinoma. Certain investigators consider that in all cases the thyroid should be removed surgically or destroyed with radio iodine, and the tumour investigated subsequently so that radio-iodine may be given in treatment if its uptake can be demonstrated (Seidlin et al 1949). It is at least desirable that radio iodine treatment should be considered for thyroid carcinomata with several years' history of slow growth, or in those shown on biopsy to be highly differentiated in histological structure with colloid formation, that radio iodine uptake should be examined where metastases are remote from the thyroid or where a thyroidectomy has been performed, that biopsy material should be examined for radioactivity where uptake appears likely but cannot be otherwise demonstrated and that where such uptake is demonstrated or strongly suspected, radio iodine treatment should be given in high initial dosage.

This discussion has been confined to certain uses of one radio element only, and has dealt entirely with human applications. In many other problems of thyroid function, and in work unconnected with the gland, radio iodine has already been of great value. The extensive clinical and other applications of radiosodium, radio phosphorus, and increasingly of radio iron are already familiar, while the radioactive forms of many other elements of biological importance and of their colloidal forms have been or are being used widely in research. I would stress particularly the advantages in clinical investigation of obtaining by the use of these radio

active isotopes a direct sample of the metabolism of the actual elements concerned, without disturbing the function that is being observed. They offer a wealth of procedures simply and safely applicable to man, provided that the hazards, particularly of large doses and long lived isotopes, are strictly controlled. Yet, for all their scope and future promise, the tracer techniques remain a method of study and not a study in themselves, just as, for example, the microscope is a research tool and not a research problem. Like it, they will be the main tool in some problems, and a subsidiary one in many problems. Their value will be fully realised when they are used alongside other and older methods of investigation and when their employment does not dominate, but is subordinated to, the plan of scientific inquiry. So used, they are likely to have a power and a versatility shared by few comparable methods of research.

SUMMARY

The circulation of iodine through the body may be examined quantitatively using radioactive iodine, and the duration of various stages of the iodine cycle compared in Graves's disease and in health.

Normally, iodide injected intravenously is distributed within 2 hours through 40% of the body weight, whence it is removed by thyroid or kidneys after a mean time of 6-8 hours. It then remains for many weeks in the thyroid, and for a few days is circulating thyroxine before re-entering the cycle (fig 8) or being excreted by the kidney.

In Graves's disease, the mean stay as iodide is 1-2 hours, that in the thyroid averages 5 days and may be less than 1 day, and 2 days are spent in circulation as thyroxine. Most of the iodine liberated from the tissues probably re-enters this cycle.

The thyroid's avidity for iodide may be measured by the rate at which it clears plasma of radio iodide. In Graves's disease this thyroid clearance rate is usually raised from a normal average of 25 ml. per minute to over 100 ml. per minute.

Iodine is at first found to be concentrated in the thyroid, in the bladder and kidneys (fig 10), and in gastric and salivary secretions. In thyrotoxic patients, after a few days some localisation may occur in the liver area (fig 11), presumably from thyroxine concentration.

The distribution of radio iodine may indicate whether a thyroid carcinoma itself concentrates iodine (fig 17) or replaces iodine concentrating thyroid tissue (fig 14).

The treatment of iodine concentrating carcinoma with radio iodine is illustrated in figs 18 and 19.

UNIT, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The long waiting period before patients with pulmonary tuberculosis can be admitted to hospital or sanatorium has produced remedial, preventive, and economic problems for the chest physicians responsible for their domiciliary care. In view of the worsening in their condition that often occurs during this wait, induction of artificial pneumothorax in the patient's home has been advocated, and evidence has been published to show that this procedure is justified and free from major risk. Thus Pritchard (1948), Toussaint (1948), and Heller (1949) have adopted it as routine treatment in suitable cases, and Hoffstaedt (1949) advocates "early ambulatory collapse treatment after the induction of collapse in sanatorium or hospital, so that the magic circle which separates" so many patients "from timely treatment will be broken."

It may be comparatively simple to carry out an effective scheme of domiciliary collapse therapy in large cities, but it is more difficult to operate such a plan in areas which are partly urban and partly rural, and the possible complications are so hazardous that we have sought for other means of domiciliary treatment. The need for frequent injections is a serious obstacle to the administration of streptomycin in the home, but sodium *p* aminosalicylate (sodium P A S), which is effective by mouth and free from major side effects, is more suitable for domiciliary use.

PLAN OF INVESTIGATION

We report here our experience with 50 cases of pulmonary tuberculosis treated at home with sodium P A S ('Paramisan Sodium') since October, 1948. The patients were classified into four groups, AB, C, D, and E, according to the type of lesion present at the start of the trial, as in table 1.

The results obtained were related to the type of lesion, the existence of complications and their treatment, the production of resistant strains of tubercle bacillus, and

TABLE 1—INITIAL CLASSIFICATION OF TREATED AND CONTROL PATIENTS

Groups	Treated with P A S		Total	Controls
	Twelve week course	Six week course

Total	23	27	50	106

* Of these 7 patients 2 were being treated with pneumoperitoneum and 5 with artificial pneumothorax (including 1 bilateral)

the possible retrogression of the lesion on cessation of treatment.

The aim was to compare the progress of the 50 patients treated with sodium P A S with that of 106 controls obtained from among patients attending the clinic at some years before September, 1948, and selected so as to be roughly similar to the treated patients in age and sex, type and extent of lesion, mode of (non chemotherapeutic) treatment, and economic and domestic conditions.

Each patient's present, past, and family history were recorded, together with the general condition, weight, and physical signs. Investigations included erythrocyte sedimentation rate (E S R), blood-counts, culture of sputum, and radiography. In old cases, the past history of the tuberculous lesion and the records of former treatment were also reviewed.

Radiologically, all the treated and control cases conformed to the definition of their group, but within these limits there were some variations. Thus the films of the treated patients in group C showed fairly extensive disease with cavitation in most cases, whereas none of the controls in group C had any cavities.

At the end of six weeks each patient in the sodium P A S series was conveyed to the clinic for a complete assessment, and in the 23 cases where the treatment was continued for a further six weeks this was followed by another complete assessment. The controls were assessed again twelve weeks after the date when they had shown signs comparable to those found initially in the treated cases. Patients in the sodium P A S series were kept at rest in bed during the trial, being allowed up only for toilet. The controls had been kept at rest in bed for twelve weeks. In both series patients in group E were brought to the clinic for collapse therapy refills.

DOSAGE

The sodium P A S was given six times a day, at 9 A M, 11 30 A M, 2 P M, 4 30 P M, 7 P M, and 9 30 P M. The daily dosage was 18 g and each 3 g dose was given in a mixture as follows:

Paramisan sodium	3 g
Syrup of orange	minims 30
Emulsion of chloroform (B P C)	minims 5
Water to	1 oz.

Tablets, each containing 0.33 g of paramisan sodium were tried in 6 cases. This involved giving 9 tablets as a dose, and a total of 54 tablets each day. Most patients preferred the mixture, so the tablets were abandoned.

If a patient complained of nausea, an alkaline mixture was prescribed. When vomiting and diarrhoea occurred, the dosage of sodium P A S was reduced temporarily to half- or a quarter and the patient was given either a 50 mg capsule of 'Benadryl' twice daily or one of the following mixtures three times a day:

(1) Prepared chalk	gr 10
Tincture of opium	minims 8
Tincture of catechu	minims 5
Peppermint water	minims 60
Water to	1/2 oz.
(2) Syrup of tolu	minims 20
Dilute hydrocyanic acid	minims 2
Solution of morphine hydrochloride	minims 10
Chloroform water to	1/2 oz.

Acquired idiosyncrasy, which developed in one patient, was treated by withholding sodium P A S altogether for forty-eight hours and then gradually increasing the four hourly dose over twelve days from 0.25 g to the full 3 g.

It was not found necessary to give potassium citrate to render the urine alkaline, for no cases developed any renal disturbance. No patient in this series had haemoptysis, so it was not thought necessary to prescribe vitamin K, but all the patients received 1 mg of vitamin B₁ daily as a routine.

Blood levels

The blood P.A.S. levels were estimated weekly by one of us (E. R. J.) by the method described by Herts Pharmaceuticals Ltd., with slight modifications. This method depends on the production of a yellow green colour by the addition of Ehrlich's reagent to solutions of P.A.S. or sodium P.A.S.

The *p*-dimethylaminobenzaldehyde used for the Ehrlich's reagent was purified from alcohol and water. All determinations were made with a 'Spekker' absorptiometer by using solutions containing 20, 10, 5, and 2.5 mg. of sodium P.A.S. per 100 ml. to produce the calibration curve and treating these solutions in the same manner as specimens of blood. The calibration curve for the dilution of sodium P.A.S. used is a straight line. All readings in the Spekker absorptiometer were made against blanks in which distilled water treated similarly took the place of blood. Most samples of blood gave a slight colour with Ehrlich's reagent, and a "blank" was estimated on every patient before the start of treatment and after its completion. The "blank" varied from the equivalent of 0 to 1.2 mg. of P.A.S. per 100 ml., and the value found has been subtracted from the P.A.S. levels found during treatment.

Other Measures

A full blood-count was made before and after the course.

PLANNED COMBINED OPERATION

Before the course of sodium P.A.S. was started a "combined operation" of the various possible methods of treatment was planned. The following is an example.

(1) Rest in bed, with ancillary nourishment and attention to economic needs.

(2) Recommendation for admission to a suitable hospital for one or more of the following: (a) continuation of rest in bed, (b) sanatorium régime, (c) artificial pneumothorax, (d) pneumoperitoneum with or without phrenic crush, (e) thoracoplasty or other surgical procedure, and (f) chemotherapy.

(3) The course of sodium P.A.S. was then started for six weeks in the first instance, and subsequently extended to twelve weeks in 23 cases.

(4) Any modification of (2) was then considered and the necessary action taken.

Further assessments of the condition of the lesions after the course of treatment are planned and will be reported on later. If the lesions are found to be retrogressing, a decision will be taken about continuation of sodium P.A.S. therapy or the institution of an alternative form of treatment.

INITIAL CONDITION

Table II shows the general condition and E.S.R. of treated and control patients in the four groups at the start of the period of observation.

It will be seen that the proportion of patients with good general condition was twice as large in the controls

as in the combined groups of patients treated with sodium P.A.S. The controls had proportionately fewer in the fair category, whereas the percentages in poor condition were the same in the two series.

A similar advantage was shown by the controls in their E.S.R., their proportion of cases with a rate of 0-20 mm in 1 hr. was twice as high as in the treated patients. The proportions in the 50+ group was similar in the two series whereas cases with intermediate rates (21-50 mm in 1 hr.) were more numerous in the treated series.

RESULTS AT END OF PERIOD

Each patient's condition was assessed on radiological appearances, general condition, weight, E.S.R., and amount of sputum and its bacillary content. The radiogram is the most important single factor to consider, and in most cases the clinical and radiological changes follow similar trends. It will be seen from table III that there was radiological improvement in 18 (78.3%) of the 23 patients treated for twelve weeks and 20 (74.1%) of the 27 treated for six weeks, whereas of the 106 controls, 38 (35.8%) showed improvement, 45 (42.5%) no change, and 23 (21.7%) deterioration.

Table III also shows that the patients with cavities at the start of treatment were more numerous in the treated series than in the controls—i.e., 43 of the 50 treated patients as against 47 of the 106 controls.

Of the patients with cavities the proportion showing improvement was about four times as large in the treated series as in the controls—i.e., 15 of the 20 patients treated for twelve weeks and 17 of the 23 treated for six weeks as against 10 of the 47 controls.

* The E.S.R. was not recorded in controls as follows

Group	Before	After
AB	5	11
C	8	8
D	12	11
E	0	0
Total	25	30

Of the patients without cavities 3 out of 3 treated for twelve weeks and 3 out of 4 treated for six weeks showed improvement as against 28 of the 59 controls

Erythrocyte sedimentation Rate

In table IV it will be seen that the E.S.R. (Westergren) showed the same trend as the radiological findings. Most of the patients to be treated with P.A.S. had a reading of 21-50 mm in 1 hr before the course. On the completion of treatment patients on both the twelve week and the six week courses showed a reduction in the reading, most of them now being 0-20 mm in 1 hr. Most of the controls had an initial reading of 0-20 mm in 1 hr, a condition that remained unchanged after three months' rest in bed.

Body weight

Table V shows that a good proportion of patients with pulmonary tuberculosis gain weight when the only treatment is rest in bed. In groups AB, C, and D of the controls most of the patients gained up to 13 lb. Only a small percentage of them lost weight. Among the treated patients this trend was not so well marked, but the figures for the twelve week course show that there was a tendency to gain weight in all the groups despite the digestive disturbance that most patients showed in the early days of treatment. Data for the six week course, however, reveal a loss of weight in 14 of the patients in all the groups, there being an increase in weight in 13 patients. The preponderance is therefore towards a gain in weight in the patients treated with P.A.S. as well as in the controls.

Toxaemia

Before the start of treatment with sodium P.A.S., 20 of the 50 patients showed severe, and 23 moderate, toxæmia. Most patients on both the twelve week and the six week courses showed a distinct reduction in toxæmia, greater than in the corresponding control groups (table VI).

Sputum

Table VII shows that at the start of treatment the sputum of most of the patients in all groups of the treated series contained tubercle bacilli. At the end of both the six week and the twelve week courses a number of patients with positive sputum had fallen considerably and there was an increase in the number with no sputum.

Among the controls, though such changes were not so well marked, the tendency was to the absence of sputum or to sputum conversion. Sputum conversion occurred in the four groups as follows:

Group	Twelve week course	Six week course	Controls
AB	1	1	3
C	1	0	2
D	0	2	5
E	0	1	3

The sputum conversion in patients treated with sodium P.A.S. confirms the statements of Vallentin (1946), Steinlin and Wilhelm (1948), and Paraf et al. (1948), all of whom have reported this reaction in some of their cases.

Morphological changes in the bacillus have been described by Nagley and Logg (1949), Dempsey and Logg (1947), and Erdei (1948). These include granulation with beading and occasional striation. The granules were acid-fast, and these bacilli could not be grown on either Dubos or solid media. Davis (1948) confirms this, saying that a concentration of 0.2-0.4 mg per 100 ml of Dubos medium inhibits the growth of tubercle bacilli from an inoculum of the H37 strain. Erdei (1948) also affirms that after three weeks' treatment cultures of the sputum showed no growth in six weeks.

The microscopical characters of tubercle bacilli found in the sputum of patients being treated with sodium P.A.S. vary considerably. In some the organisms exhibit little change in morphology, but in most cases atypical forms predominate. In the latter, clumping of the bacilli is very striking, beaded forms are numerous, and some show uneven staining. Short thick forms may be

found, and some bacilli present swellings, particularly at the ends, in which the acid fast substances stain very deeply with Ziehl-Neelsen, mycelial threads, the length of 10-12 organisms, have been observed, but definite branching is not a conspicuous feature

SENSITIVITY OF TUBERCLE BACILLI TO SODIUM P.A.S

A vital factor in the chemotherapy of tuberculosis is the tendency of tubercle bacilli to produce resistant strains during treatment. Though Davis (1948), Erdei (1948), and Lehmann (1947) did not find resistant strains, Widström and Swedberg (1948), in Sweden, have shown that treatment with sodium P.A.S. produces resistance in the tubercle bacilli in the same way as treatment with streptomycin produces resistance in tubercle bacilli against streptomycin, and they provide statistically reliable evidence of differences in behaviour of strains of tubercle bacilli according as the patients harbouring them have, or have not, been treated with sodium P.A.S. Graessle and Pietrowski (1949) have found that sodium P.A.S. can be used in vitro to retard the development of streptomycin resistant strains.

Experiments show that even in untreated cases the sensitivity of tubercle bacilli to P.A.S. varies widely. Delaude et al. (1949) found that cultures from 46 patients not treated with P.A.S. and from 18 patients treated with P.A.S. alone for 94 days or less, were resistant to only 0.006-0.012 mg of sodium P.A.S. per 100 ml of egg yolk-agar medium, and Youmans et al. (1947) state that 17 recently isolated strains of tubercle bacilli were inhibited in vitro by P.A.S. in concentrations of 0.02-0.08 mg per 100 ml. Fisher (1948) points out that the composition of the medium makes striking differences in the level at which growth is inhibited by streptomycin, but, though Hauduroy and Rosset (1948) suggest that this is not so for the media tried by them, there is reason to suppose that with P.A.S. the composition of the medium may have an effect.

To be of the greatest value to the clinician, the method of estimating the sensitivity of tubercle bacilli to any drug must be quick as well as reliable. For sputa containing many organisms more or less evenly distributed throughout the specimen the slide microculture method of Pryce (1941), using human blood lysed with an equal volume of distilled water containing various amounts of sodium P.A.S. solution as medium, will give results within a week or less. But with sputum containing few organisms the results are not so reliable, for

there is no guarantee that all the smears made from the sputum contain viable tubercle bacilli. Concentrating the specimen and obtaining a homogeneous suspension of the bacilli by the caustic soda method or by Jungman's method did not give satisfactory results, with the slide technique, on hemolysed blood with and without vitamin K, Dubos medium, blood containing Proskauer and Beck medium, and Proskauer and Beck medium alone, though positive cultures from the same specimens were obtained on Löwenstein's medium.

The method now on trial is the inoculation of Löwenstein's medium, to which have been added various amounts of sodium P.A.S. solution before inspissation, with specimens concentrated by the caustic soda method.

In view of variations in the sensitivity of tubercle bacilli to P.A.S. it is advisable to test their sensitivity in every patient before starting treatment, but owing to lack of a suitable method this was not done in the present cases.

The results given below were obtained from tests made by smearing glass slides $3 \times \frac{1}{2}$ in to within $\frac{1}{2}$ in of the top of the slide with a loopful of the specimen and incubating at 37°C for 3-7 days in 1 oz screw capped bottles containing 8 ml. of the culture medium (equal parts of human blood and sterile distilled water containing sodium P.A.S. solutions to give final concentrations of 10.0, 1.0, 0.5, 0.25, 0.1, 0.05, and 0.025 mg per 100 ml of culture fluid).

Thirty specimens of sputum from 28 patients under treatment with sodium P.A.S. and controls from 3 tuberculous patients not receiving the drug were examined. The specimens were stained and examined for tubercle bacilli before culturing. The following results were obtained.

Of the controls 2 grew no tubercle bacilli in the presence of sodium P.A.S. 0.25 mg per 100 ml., but did so in the presence of 0.1 mg per 100 ml. The third did not grow tubercle bacilli in the presence of sodium P.A.S. 0.5 mg per 100 ml., but did so in the presence of 0.25 mg per 100 ml.

Of the 30 specimens of sputum from 28 patients treated with sodium P.A.S., 17 did not show tubercle bacilli on staining. 18 of these gave no growth in any dilutions of sodium P.A.S. or on the control medium, and the remaining 1 grew tubercle bacilli both in sodium P.A.S. and in the control medium. The 13 other specimens of sputum were proved by staining to contain tubercle bacilli, 3 of these gave no growth in any dilution of sodium P.A.S., or on the control medium, whereas 10 gave a growth both in sodium P.A.S. and on the control medium. Of the last-mentioned 10 specimens 1 showed growth in

1 mg per 100 ml but no growth with 10 mg, 1 showed growth in 0.25 mg per 100 ml but no growth with 0.5 mg, 4 showed growth in 0.1 mg per 100 ml but no growth with 0.25 mg, 1 showed growth in 0.05 mg per 100 ml but no growth with 0.1 mg, 3 showed growth in 0.025 mg per 100 ml but no growth with 0.05 mg.

These findings support the view that there is normally a great variation in the sensitivity of tubercle bacilli to sodium P.A.S.

Salicylism COMPLICATIONS OR SIDE EFFECTS

Lehmann (1946) has stated that none of the usual effects of salicylates (sweats and tinnitus) were observed in any of his cases, and apart from transient headaches in 2 cases these symptoms have not occurred in the present series.

Hæmaturia and Albuminuria

Hæmaturia was not seen in the present cases, but albuminuria was found in 1 case. Both hæmaturia and albuminuria occurred in 4 of the 37 cases reported by Nagley and Logg (1949). Albuminuria was found in 1 case by Hemming and Stewart (1949), who believe that, though the kidney tissues were not irreparably damaged by P.A.S., the glomeruli were affected in some way allowing increased filtration of proteins. These workers therefore advocate that P.A.S. should not be given when "there is evidence of generalised disease of the nephrons". Albuminuria has also been reported by Vallentin (1946) and Aln and Difs (1947).

Normoglycæmic Glycosuria

Zarafonets et al (1948) found glucose in the urine of patients treated with *p*-aminobenzoic acid, and Kelemen and Halmágyi (1949) found glucose in the urine of patients treated with sodium P.A.S. The latter workers report that during the excretion of the glucose kidney alkaline phosphatase activity was significantly enhanced, and on the basis of their experiments conclude that sodium P.A.S. gives rise to normoglycæmic glycosuria in some cases, and to an unknown metabolite in the urine in others.

Hypoprothrombinæmia

Swanson (1949), who used P.A.S. in rheumatoid arthritis, reports that 5 out of 6 patients developed hypoprothrombinæmia, but not enough to cause hæmorrhage. This may explain the frank hæmaturia reported by Nagley and Logg (1949), but the hæmaturia may be due to the deposit of crystals in the urinary tract. This condition cleared on alkalinisation of the urine, and O'Connor (1949) suggests the prophylactic administration of vitamin K, which suggestion is supported by the fact that Link et al. (1943) found hæmorrhages and hypoprothrombinæmia in rats when the diet was deficient in vitamin K. Erdei and Snell (1948) affirm that the excretion of ascorbic acid is greatly increased by salicylates, and advocates repeated checks on the blood-prothrombin levels and ascorbic acid excretion rate.

In the present series there has been no evidence of hæmaturia, and no patient had hæmoptysis or stained sputum during the course.

Acquired Idiosyncrasy

Hemming and Stewart (1949), Horne (1949), and Joules and Nassau (1949) all report cases of acquired idiosyncrasy to freshly made sodium P.A.S. The characteristic symptoms include malaise, anorexia, nausea, headache, intense photophobia with suffused conjunctivæ, fever, restlessness, an erythematous or morbilliform rash, itchiness of the skin, and a non-productive cough. These symptoms ceased when the drug was withdrawn, and benadryl 100 mg two or three times daily accelerated the relief. No previous history suggesting allergy was obtained. Desensitisation was obtained by giving benadryl and grading the dosage of sodium P.A.S.

Idiosyncrasy was found in 1 patient in the present series. Four weeks after the start of treatment the patient developed a temperature of 101°F, with headache, sweats, and erythematous eruption on the trunk. Sodium P.A.S. was discontinued for two days and then given again. Temperature again rose to 100°F, but fell again when drug was discontinued. Treatment was resumed a week later, beginning with a quarter of the dose three times daily. This was increased by one dose daily until six doses were being taken. The dose was next increased to half the normal dose six times daily, and, there being no further reaction on this dosage, a further increase to three quarters of the normal dose was made. This also showed no ill effects, and the full dosage was resumed with no further reaction. Benadryl 50 mg was also given twice daily for the first 3 days and then discontinued.

Another case of intolerance to sodium P.A.S. occurred two weeks' treatment and produced a syndrome resembling scarlatina, with high temperature, sore throat, serous or rhœa, labial herpes, and an erythematous eruption involving the whole of the body and causing complete desquamation of the skin. The drug was discontinued immediately in the belief that the condition was scarlatina. It is now believed that the patient had a streptococcal infection which produced a severe intolerance of salicylates. It was impossible to renew treatment with P.A.S., and this case is not included in the present series.

Gastro intestinal Upset

Symptoms of nausea, vomiting, and diarrhœa have been described by Nagley and Logg (1949), Vallentin (1946), Aln and Difs (1947), Joules and Nassau (1949), Dempsey and Logg (1947), and Sivière (1948), but Erdei and Snell (1948) report no gastro intestinal symptoms in their series.

In the present series digestive disturbances occurred in 12 of the 23 patients in the twelve week course and in 14 of the 27 patients in the six week course. The control had no gastro intestinal upset. It was not necessary in any treated case to discontinue the sodium P.A.S. even for a day owing to digestive disturbances. In a few cases the full dosage was reduced to half for one or two days until the symptoms had disappeared when full dosage was resumed. In addition, one of the mixtures mentioned above or benadryl was prescribed, and to these forms of medication all the patients responded.

DISCUSSION

The results of this trial indicate that sodium P.A.S. is of definite value in certain types of pulmonary tuberculous lesions, but it should be given with a "definite goal in view" (Nagley and Logg 1949).

It has been established in this series of cases balance against controls with similar lesions and economic and domestic conditions that definite improvement may be obtained in the general condition, toxæmia, E.S.R., sputum, radiological appearances, and, to a more limited extent, in the body-weight. Radiologically, the infiltrative process is arrested, and in most cases the cavities shrink. The disappearance of infiltrations sometimes shows that what appeared to be a single cavity in the original film is two or more cavities close together.

Exudative tuberculous lesions, whether acute or chronic, responded best, and there is evidence that longer administration of P.A.S. would be of value in supporting already existing collapse therapy not only by acting on the lesion in the partially collapsed lung but also by arresting secondary involvement of the other lung.

There is no doubt also that sodium P.A.S. is of immediate value in preparing the patient for collapse therapy. The improvement shown in the present series indicates that the drug is most efficacious in building up the patient for subsequent thoracoplasty, especially when there is no delay in submitting the patient to operation. The evidence also indicates that such premedication may also be of value in preparing patients for artificial pneumothorax, though perhaps caution should be exercised in deciding the length of time that should elapse.

fore its induction Dr F Temple Clive (personal communication) has emphasised that, in the present state of our knowledge, the result of P.A.S. therapy may possibly give a false picture of the patient's natural resistance, and that an artificial pneumothorax induced so soon after the course of treatment might be fraught with danger. Erdei and Snell (1948) have stated that there is an exacerbation of chronic lesions after the end of the course but give no indication of the length of time that ensues before such a reactivation occurs.

The experience of other workers in relation to complications arising during the course have not been shared in the present series. Gastrointestinal upsets have formed the main difficulty, but these have readily responded to general treatment. One patient gave a mild allergic response but made a rapid recovery, being desensitised by repeated small doses. One other case of a severe intolerance occurred, but it has been impossible to include this history in the series, the patient being still under treatment.

As a result of protracted laboratory investigation only one patient was found to have produced a resistant strain of tubercle bacillus. This patient's sputum was positive at the start of the course, and at the end of the course there was no sputum. A month later a positive sputum was found which was resistant to P.A.S. No other case showed production of a resistant strain. Changes in the morphology of the tubercle bacillus have been found to be common, in agreement with the experience of other workers.

Blood P.A.S. levels were estimated weekly in the patients receiving sodium P.A.S., but owing to the making of domiciliary visits at different times the blood was taken at varying intervals after the previous dose of sodium P.A.S., which fact explains the low average levels in some cases. Unless consideration is given to this time factor and the renal excretory rate, it is impossible to make a definite observation on the relationship between the average blood P.A.S. level and the final result.

SUMMARY

The domiciliary use of sodium P.A.S. in the treatment of 50 patients with pulmonary tuberculosis is reviewed. 23 patients received the treatment for twelve weeks and 27 for six weeks. These cases were reviewed against 106 controls with similar lesions and economic conditions.

Most of the patients in both series definitely improved, a fact which justified the continued use of sodium P.A.S. as part of a planned combined operation.

A resistant strain of tubercle bacillus developed in 1 case.

The reactions of the tuberculous process after the end of sodium P.A.S. treatment are being observed and will be reported later. In this further survey the haematological findings before, at the end of, and three months after the end of the course of P.A.S. will be reviewed.

Our thanks are due to the members of the staffs of the Chest Clinic of the Mid Kent Area (Maidstone) and the Kent County Laboratory, and the pharmacist at the West Kent General Hospital, for their unfailing co-operation and assistance, without which this report could not have been produced.

A CASE OF BRILL'S DISEASE IN LONDON

J C HAWKSLEY

C.B.E., M.D. Lond.,

Ph.D. Birm., F.R.C.P.

PHYSICIAN

UNIVERSITY COLLEGE HOSPITAL

E JOAN STOKES

M.B. Lond.,

M.R.C.P.

BACTERIOLOGIST

Brill's disease is a mild form of typhus fever that occurs sporadically among the immigrant populations of New York, Boston, and other coastal towns of the north eastern United States.

NATURE OF DISEASE

Brill (1898, 1910) observed between 1896 and 1910, among the Jewish patients at the Mount Sinai Hospital in New York, over 200 cases of a disease which he differentiated from typhoid fever and the other febrile conditions common to the region. The clinical suspicion that "Brill's disease" was a mild endemic form of typhus fever was confirmed by the experimental work of Anderson and Goldberger (1912) who showed that in monkeys the virus of Brill's disease and that of epidemic Mexican typhus (tabardillo) were identical, and similar in all respects to the virus of the classical louse borne typhus of Europe and North Africa. When the Weil-Felix reaction with *Proteus* OX19 was applied to cases of Brill's disease it was also found to be positive.

Extensive studies by Maxcy and Havens (1923) and Maxcy (1926a and b, 1928) revealed the occurrence throughout the southern and south-eastern United States of a disease which resembled typhus clinically, and gave a positive Weil-Felix reaction with *Proteus* OX19, but was not transmitted by the louse. The disease was referred to as endemic typhus of the United States, or Brill's disease, and Maxcy suspected on the basis of his epidemiological investigations that rats or mice were the most likely reservoirs of the infection. Similar observations were made at about the same time in Australia (Hone 1922), in the Federated Malay States (Fletcher and Lesslar 1925) and in many other parts of the world.

During 1928 and 1929 Mooser, working in Mexico City, demonstrated in a series of brilliant experiments that endemic Mexican typhus and Old World louse borne typhus could be distinguished by the different pathological effects the two infections produced in guinea-pigs and white rats (Mooser 1928, 1929). Almost immediately Maxcy (1929) was able to show that endemic typhus of the south eastern United States, which up to that time was still called Brill's disease, behaved in the same way as Mexican typhus. Maxcy's conclusion that a reservoir of the infection might exist in rats or mice was soon amply corroborated. Dyer et al. (1931) showed that the infection could be transmitted by the fleas of rats trapped in typhus foci in Baltimore, and Mooser, Castaneda, and Zimsser (1931) found that the virus was present in the brains of rats caught in Mexico City. Murine typhus, due to *R. mooseri*, is now known to have a world-wide distribution.

Meanwhile the position of what had been originally called Brill's disease—namely the sporadic typhus cases

1 mg per 100 ml but no growth with 10 mg, 1 showed growth in 0.25 mg per 100 ml but no growth with 0.5 mg, 4 showed growth in 0.1 mg per 100 ml but no growth with 0.25 mg, 1 showed growth in 0.05 mg per 100 ml but no growth with 0.1 mg, 3 showed growth in 0.025 mg per 100 ml but no growth with 0.05 mg.

These findings support the view that there is normally a great variation in the sensitivity of tubercle bacilli to sodium P.A.S.

Salicylism COMPLICATIONS OR SIDE EFFECTS

Lehmann (1946) has stated that none of the usual effects of salicylates (sweats and tinnitus) were observed in any of his cases, and apart from transient headaches in 2 cases these symptoms have not occurred in the present series.

Hæmaturia and Albuminuria

Hæmaturia was not seen in the present cases, but albuminuria was found in 1 case. Both hæmaturia and albuminuria occurred in 4 of the 37 cases reported by Nagley and Logg (1949). Albuminuria was found in 1 case by Hemming and Stewart (1949), who believe that, though the kidney tissues were not irreparably damaged by P.A.S., the glomeruli were affected in some way allowing increased filtration of proteins. These workers therefore advocate that P.A.S. should not be given when "there is evidence of generalised disease of the nephrons." Albuminuria has also been reported by Vallentin (1946) and Alin and Difs (1947).

Normoglycæmic Glycosuria

Zarfonets et al (1948) found glucose in the urine of patients treated with *p* aminobenzoic acid, and Kelemen and Halmágyi (1949) found glucose in the urine of patients treated with sodium P.A.S. The latter workers report that during the excretion of the glucose kidney alkaline phosphatase activity was significantly enhanced, and on the basis of their experiments conclude that sodium P.A.S. gives rise to normoglycæmic glycosuria in some cases, and to an unknown metabolite in the urine in others.

Hypoprothrombinæmia

Swanson (1949), who used P.A.S. in rheumatoid arthritis, reports that 5 out of 6 patients developed hypoprothrombinæmia, but not enough to cause hæmorrhage. This may explain the frank hæmaturia reported by Nagley and Logg (1949), but the hæmaturia may be due to the deposit of crystals in the urinary tract. This condition cleared on alkalinisation of the urine, and O'Connor (1949) suggests the prophylactic administration of vitamin K, which suggestion is supported by the fact that Link et al (1943) found hæmorrhages and hypoprothrombinæmia in rats when the diet was deficient in vitamin K. Erdei and Snell (1948) affirm that the excretion of ascorbic acid is greatly increased by salicylates, and advocates repeated checks on the blood prothrombin levels and ascorbic acid excretion rate.

In the present series there has been no evidence of hæmaturia, and no patient had hæmoptysis or stained sputum during the course.

Acquired Idiosyncrasy

Hemming and Stewart (1949), Horne (1949), and Joules and Nassau (1949) all report cases of acquired idiosyncrasy to freshly made sodium P.A.S. The characteristic symptoms include malaise, anorexia, nausea, headache, intense photophobia with suffused conjunctivæ, fever, restlessness, an erythematous or morbilliform rash, itchiness of the skin, and a non-productive cough. These symptoms ceased when the drug was withdrawn, and benadryl 100 mg two or three times daily accelerated the relief. No previous history suggesting allergy was obtained. Desensitisation was obtained by giving benadryl and grading the dosage of sodium P.A.S.

Idiosyncrasy was found in 1 patient in the present series. Four weeks after the start of treatment the patient had a temperature of 101°F, with headache, sweats, and erythematous eruption on the trunk. Sodium P.A.S. was discontinued for two days and then given again. Temperature again rose to 100°F, but fell again when drug was discontinued. Treatment was resumed a week later, beginning with a quarter of the dose three times daily, and was increased by one dose daily until six doses were taken. The dose was next increased to half the dose six times daily, and, there being no further rise on this dosage, a further increase to three quarters of normal dose was made. This also showed no ill effect: the full dosage was resumed with no further symptoms. Benadryl 50 mg was also given twice daily for the first days and then discontinued.

Another case of intolerance to sodium P.A.S. occurred two weeks' treatment and produced a syndrome resembling scarlatina, with high temperature, sore throat, serous rhœn, labial herpes, and an erythematous eruption involving the whole of the body and causing complete desquamation of the skin. The drug was discontinued immediately on the belief that the condition was scarlatina. It is now believed that the patient had a streptococcal infection which produced a severe intolerance of salicylates. It was impossible to renew treatment with P.A.S., and this case is not included in the present series.

Gastro intestinal Upset

Symptoms of nausea, vomiting, and diarrhœa have been described by Nagley and Logg (1949), Vallentin (1946), Alin and Difs (1947), Joules and Nassau (1949), Dempsey and Logg (1947), and Sivrière (1948), but Erdei and Snell (1948) report no gastro intestinal symptoms in their series.

In the present series digestive disturbances occurred in 12 of the 23 patients in the twelve week course and in 14 of the 27 patients in the six week course. The control had no gastro intestinal upset. It was not necessary in any treated case to discontinue the sodium P.A.S. even for a day owing to digestive disturbances. In a few cases the full dosage was reduced to half for one or two days until the symptoms had disappeared when full dosage was resumed. In addition, one of the mixtures mentioned above or benadryl was prescribed, and to these forms of medication all the patients responded.

DISCUSSION

The results of this trial indicate that sodium P.A.S. is of definite value in certain types of pulmonary tuberculosis lesions, but it should be given with a "definite goal in view" (Nagley and Logg 1949).

It has been established in this series of cases balanced against controls with similar lesions and economic and domestic conditions that definite improvement may be obtained in the general condition, toxæmia, E.S.R., sputum, radiological appearances, and, to a more limited extent, in the body weight. Radiologically, the infiltrative process is arrested, and in most cases the cavities shrink. The disappearance of infiltrations sometime shows that what appeared to be a single cavity in the original film is two or more cavities close together.

Exudative tuberculous lesions, whether acute or chronic, responded best, and there is evidence that longer administration of P.A.S. would be of value in supporting already existing collapse therapy not only by acting on the lesion in the partially collapsed lung but also by arresting secondary involvement of the other lung.

There is no doubt also that sodium P.A.S. is of immense value in preparing the patient for collapse therapy. The improvement shown in the present series indicates that the drug is most efficacious in building up the patient for subsequent thoracoplasty, especially when there is no delay in submitting the patient to operation. The evidence also indicates that such premedication may also be of value in preparing patients for artificial pneumothorax, though perhaps caution should be exercised in deciding the length of time that should elapse.

rols of the suspensions were included in each test. Having obtained positive results with this method on the first two suspensions it was used throughout the investigation.

The results of the Weil-Felix tests were not considered altogether satisfactory, and seven samples of serum were sent to Dr A. Felix for further investigation. His findings of the agglutination tests are shown in table II, and his interpretation of the results was that the marked drop in the OX19 titre was to be accepted as confirming a clinical diagnosis.

Dr Felix also examined the sera for agglutinins against typhoid and louse borne rickettsiae, but the suspensions in his collection, which had been obtained from Dr J. Craigie, Toronto, nearly three years ago, proved to be inert. He therefore sent five of the sera to Dr Joseph E. Smadel, Department of Virus and Rickettsial Diseases, Army Medical Center, Washington, for rickettsial agglutination and complement-fixation tests. A report on them was received from Dr Ross L. Gauld (table III) who interpreted the results as follows:

"The reactions in this case are definitely epidemic in type and are consistent with a diagnosis of Brill's disease. The final diagnosis, of course, must rest upon the epidemiological evidence. It is the experience of this laboratory that the rickettsial agglutination generally becomes positive before the complement-fixation. We have no adequate explanation to offer for the delay in the appearance of a positive agglutination test in this case."

We are very grateful to Dr Felix, to Dr Smadel, and to Dr Gauld for their interest and help. An accompanying paper by Dr Felix comments on the findings.

NOTE ON

A CASE OF BRILL'S DISEASE IN LONDON

A. FELIX

D.Sc., F.R.S.

DIRECTOR, CENTRAL ENTERIC REFERENCE LABORATORY AND BUREAU, PUBLIC HEALTH LABORATORY SERVICE (MEDICAL RESEARCH COUNCIL), LONDON

THE identification in London of a case of Brill's disease, described in the accompanying paper by Hawksley and Stokes will interest clinician, epidemiologist, and laboratory worker alike. So far as I am aware, only one case had previously been identified in a reliable manner outside the coastal towns of the north-eastern United States. That single case occurred in 1945 in Zürich (Mooser and Löffler 1946) in an Armenian, aged 52, who arrived in Switzerland in 1939 and gave a history of having had severe typhus fever in South Russia in 1918. Mooser's wide experience of typhus fever may be accepted as a guarantee that the Zürich case was one of Brill's disease — i.e., genuine recrudescence of louse borne typhus after an interval of many years (Zinsser 1934).

In Zinsser's (1934) statistical study of 538 cases of Brill's disease diagnosed in New York and Boston in the course of thirty years, over 90% of the patients were Jewish immigrants from eastern Europe. There was,

of course, no reason to assume that the incidence of the disease was limited to any racial group. More recently 2 serologically proved cases of Brill's disease have been reported in Irish born residents of Boston (Morgan et al. 1948). Both patients had been born in Co. Galway, Ireland, where outbreaks of louse borne typhus are known to have occurred up to quite recent times (McConn 1943), but both had lived in Boston for more than thirty years. It is obvious that Brill's disease will occasionally be seen in any country whose population comprises an appreciable proportion of persons previously exposed to louse borne typhus. This, of course, applies equally to countries that are endemic areas of louse borne typhus and to countries that receive immigrants from those areas.

The clinical diagnosis of typhus is not altogether easy, and the most experienced physician may be unable to diagnose mild cases of the disease, even during an outbreak. Naturally the difficulties of diagnosis are much greater in a country where the disease is unknown or very rare, and in Brill's disease they are further increased by the fact that the cases always occur sporadically, and that the clinical course is as a rule milder than in the primary attack of louse borne typhus. This has been brought out vividly in a comprehensive study published a few weeks ago by a group of workers in New York and Boston (Murray et al. 1950), some of whom command an unrivalled personal experience of the treatment of Brill's disease. The patient now diagnosed in London failed to develop even a rash, the most helpful of the few diagnostic criteria, and the accuracy of the clinical diagnosis was in this case undoubtedly due to the fact that the attending physician had acquired considerable experience of typhus fever while serving with the Army in the Middle East.

It is not surprising, therefore, that laboratory tests are indispensable in the diagnosis of cases of Brill's disease. Since the war of 1939-45 agglutination and complement-fixation tests with rickettsial suspensions have become available, in addition to the old established tests with *Proteus* OX antigens. The rickettsial tests have the great advantage of making it often possible to distinguish between those varieties of typhus which give overlapping reactions to the *Proteus* OX antigens and which, therefore, cannot be differentiated by the Weil-Felix test. Rickettsial antigens are, however, rather delicate and expensive reagents, and their use is of necessity restricted to certain central institutes, the average routine laboratory must continue to rely on the simple agglutination test with *Proteus* OX antigens. The present case of Brill's disease in London clearly showed that it was possible to confirm the clinical diagnosis by the use of the *Proteus* OX19 reaction. Comparison of tables II and III in the accompanying paper also shows that in this particular case the OX19 reaction was positive earlier than the rickettsial agglutination test.

Even the relatively simple agglutination test with *Proteus* OX antigens must, however, be carried out according to the proper technique, if reliable results are to be obtained. The customary Dreyer's technique, still recommended in most textbooks, is unsuitable for this test, because of the heat lability of O agglutinins (Weil and Felix 1917, Felix and Oltzka 1929). This is clearly demonstrated by tables I and II. The proper technique is the one using round bottomed tubes and incubation at 37°C (Felix 1944). The necessity for standardising these tests by international agreement has been stressed recently (Felix 1950), and the suggestion that "international serum standards" be adopted has been accepted by the Expert Committee on Biological Standardisation of the World Health Organisation (1950).

How great is the need for standardising these tests is shown by the observations on 14 cases of Brill's disease published by Murray et al. (1950). These workers found that "only 3 of the 14 patients had a diagnostic agglutina-

among the urban immigrant population in the north eastern United States—remained obscure. Its epidemiology was compatible with transmission by neither

Chart from admission to hospital on eighth day of illness

Subsequently Zinsser and Castaneda (1933) isolated from a case of Brill's disease in Boston a typhus strain that was clearly of the European louse borne variety and Zinsser (1934) concluded from statistical investigation that the cases of Brill's disease observed in New York and Boston represented recrudescences of old infections originally acquired in European foci.

This rather surprising explanation of the nature of Brill's disease was not generally accepted until recent

TABLE I—LABORATORY INVESTIGATIONS

Sept. 22—Blood count: total white cells 10,000; neutrophils 62%, lymphocytes 33%, monocytes 4%, and eosinophils 1%.
Sept. 27 to Oct. 9—Four faeces cultures all negative for salmonella, shigella, and Proteus.
Sept. 21 to Sept. 23—Two catheter specimens of urine normal.
Sept. 23—Aerobic and anaerobic blood-cultures remained sterile during three weeks incubation.
Sept. 24 and 29—Widal and Brucella abortus agglutination tests negative.

Weil-Felix Tests Agglutination Titres

advances in the serology of the typhus group provided convincing evidence in support of Zinsser's observations. By the use of complement fixation tests with murine and louse borne rickettsia, Plotz (1943) was able to show beyond any doubt that New York cases of Brill's disease give the same reactions as those obtained in cases of Old World louse borne typhus.

The immigrants who develop Brill's disease in the United States usually give a history of having had typhus while in Poland or Russia. Evidently *R. prowazeki*, the causative agent of louse borne typhus, persists indefinitely in some recovered typhus patients,

and when the resistance is lowered induces a mild attack of the disease.

THE PRESENT CASE

Mrs. A., aged 49, began to complain of headache and pains in her limbs while she was at work on Sept. 11, 1948. The pains got worse and were not confined to joints, being felt throughout the limbs. Insomnia was present from the onset. She consulted her doctor on Sept. 18 and was found to have a temperature of 101°F. Sulphadimidine ('Sulphamezathine') was given without effect. Her symptoms had not changed by the eighth day of illness and she was admitted to hospital on Sept. 20. Her condition was then satisfactory.

TABLE II—RESULTS OF WEIL-FELIX TESTS CARRIED OUT AT THE CENTRAL ENTERIC REFERENCE LABORATORY, PUBLIC HEALTH LABORATORY SERVICE, COLINDALE*

* The tests were carried out according to the technique described by Felix (1944) using suspensions prepared at the Standards Laboratory for Diagnostic Reagents, Public Health Laboratory Service, Colindale.

temperature 102.4°F, pulse rate 94, respiration normal. She was irritable and the taking of her history was difficult. There was no rash, the mouth was normal and the tongue moist, the spleen was not palpable, and the only other physical signs of disease were scattered rhonchi in the chest. There was, however, suffusion of the conjunctivae and the pupils appeared slightly contracted. No particular smell was noticed.

The patient was born in Poland and had typhus there in 1915 (She remembers the rash, that she was in coma a considerable number of days, and that all her hair was shaved off). She migrated to Berlin when 19 years old and came to England in 1939.

The fever, and the symptoms, remained unchanged for four days. On the fifth the temperature began to fall and by the eighth she was afebrile (see figure) and feeling weak but otherwise better.

A tentative diagnosis of Brill's disease was made, and investigations were undertaken (table I). All were negative except the Weil-Felix tests.

The first two Weil-Felix tests were done by the same technician using the same suspensions that had been prepared a few days previously by diluting the Standards Laboratory concentrated suspensions 1 in 15 and storing them in the refrigerator. The readings were checked by one of us (E.J.S.). All the subsequent tests were made using the Standards Laboratory concentrated suspensions diluted freshly on each occasion 1/15 in physiological saline. Equal volumes of the diluted suspensions and the serum dilutions to be tested were set up in Dreyer's tubes and incubated in a 50°C water bath for four hours. They were then allowed to stand at room temperature overnight and read in the morning. Saline

THE LANCET

LONDON SATURDAY, JULY 15, 1950

Accuracy in Red-cell Counts

WHEN the physician asks the laboratory for a red cell count on an anæmic patient he will often rely largely on their findings for both diagnosis and the control of treatment. Much weight is also placed on the colour-index, which shows whether the red cells contain more or less hæmoglobin than normal, and the value of this index depends on the reliability of the red-cell count. Yet for over forty years the accuracy of red cell counts has been criticised. In 1906 "Student"¹ showed that there is an irreducible statistical error in counting red cells, or any similar particles, which is roughly inversely proportional to the square root of the number counted, when 500 cells are counted, this error amounts to about 4%. Other errors are likely to arise but can be minimised. One is the error of sampling, since a single drop is taken to be a representative sample of the patient's whole blood, then calibrated instruments are likely to vary, particularly dilution pipettes, errors of technique, such as tying a tourniquet round a finger and squeezing out the blood, will be significant unless technicians are properly trained, and finally, operators differ in the skill with which they judge the filling of pipettes or count cells in the counting-chamber, for example. Thus, when BERKSON and colleagues² did a series of red-cell counts with the usual apparatus, paying as much attention to avoidable errors as they could, it was not surprising that their minimum error was greater than the statistical 4%. They used a single pipette and one counting chamber and counted the cells in 80 small squares of the ruled area, which is the usual practice. They found that with a normal count of 5,000,000 per c mm, when 500 cells were counted in the 80 squares, the coefficient of variation was 7.8%. This expresses the minimum error, the probable limit of error, which will not be overstepped more than once in 20 times, is usually taken to be twice the minimum error, in this case $\pm 16\%$. This is a very wide range. In practice it means that a count of 5,000,000 may be obtained from a patient who in fact has anything between 4,200,000 and 5,800,000 red cells per c mm. Similarly, with a count of 4,000,000 the range is 3,360,000 to 4,640,000 per c mm.

Calculations of this kind have not deterred clinicians from using the red cell count, and such estimates of the probable range of error have been strongly contested. WINTROBE,³ for example, states in his textbook that, with trained technicians, "it will be found that, with practice, counts agreeing within 200,000 cells per c.mm can be made." This has been

the general opinion among clinical pathologists, and they have acted on it. In 1948 BIGGS and MACMILLAN⁴ re-examined the question. BERKSON and colleagues had used photographs of microscope fields for counting red cells in the counting chamber, BIGGS and MACMILLAN had the counting done directly, as in practice. With five observers, ten pipettes, and ten chambers their minimum error was 9.46%—somewhat larger than that of BERKSON et al. With this degree of error, if a patient's initial count is 2,000,000 per c mm, subsequent counts must be under 1,400,000 or over 2,600,000 before a significant fall or rise can be claimed. This range of error is larger than that of other methods of assessing anaemia, apart from the colour-index and the mean cell volume, which necessarily reflect the inaccuracy of the red cell count.

Thus for hæmoglobin, BIGGS and MACMILLAN put the minimum error at 5.2% with the Haldane method and 3.3% with the neutral grey wedge method, whereas for the hæmatocrit it is only 0.5%. They therefore concluded that laboratories were wasting their time in doing red cell counts at all, and in training technicians to do them. They proposed to assess anemia by determining the hæmoglobin and the hæmatocrit and hence calculating the mean corpuscular hæmoglobin concentration (MCHC). But the MCHC is normally at maximum, it may vary below, but not above, the normal value. Consequently, in macrocytic anæmias, further information is needed, BIGGS and MACMILLAN proposed to get this by estimating the mean red cell diameter, and if the estimate is to be reasonably accurate it must be based on a Price Jones curve. This is likely to prove a serious obstacle in the campaign for more accurate assessment of anæmia in the clinic. For a Price-Jones curve takes at least half an hour to construct, and the equipment is not commonly found in clinical laboratories. Unfortunately it is in the macrocytic anæmias that the clinician most often needs quick results for prescribing future treatment or assessing the activity of liver extracts or similar materials. Much of this work is done in outpatient clinics, and few clinical laboratories could meet a demand for ten to twenty Price Jones curves at one time. Yet the position cannot be left where it is. If in a patient with pernicious anæmia the red-cell count falls from 4,000,000 to, say, 3,200,000 per c mm., the clinician will certainly infer that a relapse is imminent and raise the dosage. Again, claims for the activity of anti-anæmic materials have been based on an increase in red cells from 2,000,000 to 2,500,000 per c mm. Yet such changes as these are within the range of error of counts done under the best conditions.

To dispense with the red-cell count altogether would clearly impair our assessment of anaemia, because it cannot be readily replaced. And the immense inertia of generations of clinicians accustomed to use the red cell count and the colour-index must be taken into practical account. There is good reason, therefore, for the renewed efforts being made to improve the accuracy of red cell counting by adopting electronic methods of counting particles. By such methods large numbers of cells can be counted in a very short time, so reducing the statistical error. Elimination of the human element in the actual

tion titre in the Weil-Felix test," and "that this test in the majority of cases is more apt to be misleading than helpful." Murray et al did not state what technique they employed in the OX19 agglutination test, but a glance at their tables 4 and 5 shows that in 12 of the 14 cases a negative result had been obtained at some stage of the disease, or throughout its course, in a dilution as low as 1 in 10. This is contrary to what has been firmly established by investigations conducted in nearly all parts of the world in regard to so-called normal OX19 agglutinins, and indicates that the technique employed was unsatisfactory, because it evidently reduced the sensitivity of the test far below the permissible minimum. Murray et al also quote Blattels (1928) and Schoenbach (1949) as having noted negative Weil-Felix reactions in Brill's disease. The former examined 45 cases during 1920-28 and observed only 2 positive reactions, but his paper does not give any indication of titres or technique employed, and it is known from the careful investigations by Spencer and Maxey (1930) and Davis and Parker (1932) that unsuitable cultures and methods were in use in the test in the United States at that time. The same criticism applies to the paper by Schoenbach (1949), who described negative *Proteus* OX19 reactions in a case of Brill's disease in Baltimore without stating titres or technique. Morgan et al (1948), on the other hand, were apparently well aware of the pitfalls and had the sera examined from their 2 cases of Brill's disease simultaneously in two laboratories. In one of their cases the Army Medical Laboratory, Washington, reported OX19

titres 8 times higher than those recorded at the E City Hospital. In the London case of Brill's disease the tests carried out in two laboratories showed a fourfold difference in titre (tables I and II).

From the epidemiologist's point of view, Brill's disease is of interest as a possible source of dissemination of louse-borne typhus. In the series of 14 patients investigated by Murray et al (1950) *Rickettsia prowazekii* was isolated by louse feeding in half the cases, a remarkable achievement accomplished by perfect teamwork between laboratory workers and clinicians. In view of the widespread epidemics of louse-borne typhus during the war of 1939-45 and the post-war movement of large groups of people from one country to another, it is likely that cases of Brill's disease may come to prominence in many parts of the world.

Reviews of Books

The Child in Health and Disease

Editors CLIFFORD G GRULEE, M.D., Rush professor of pediatrics, University of Illinois, R CANNON ELEY, M.D., associate in pediatrics and communicable diseases, Harvard University Medical School, Baltimore
 Williams & Wilkins London, Baillière, Tindall, & Cox 1948 Pp 1070 66s

THIS new American textbook on paediatrics has been compiled by no fewer than seventy-five contributors under the editorship of two eminent paediatricians—Prof Clifford Grulee, of the University of Illinois, and Dr Cannon Eley, of Harvard University and the Children's Hospital, Boston. The work was undertaken some years ago, but the war interrupted it and all the manuscripts had to be rewritten. The writers have achieved a comprehensive and well-balanced book in which clinical and scientific paediatrics are happily blended. The volume is divided into nineteen sections, beginning with physical and mental development, nutrition, the newborn, and prematurity. The latter part of the book consists of sections on the eye, the teeth, adolescence (a welcome addition to a paediatric textbook), and paediatric surgery. This "textbook for students and practitioners of medicine" is authoritative and up to date.

Traitement chirurgical de l'otospongiose

MATTHEE SOURDILLE, professeur de clinique oto-rhino-laryngologique à la Faculté de Médecine de Strasbourg
 Paris Masson. 1948 Pp 253 Fr 750

Professor Sourdille has been a successful pioneer in the treatment of deafness by surgery, and this book is a collection of his writings on the subject. The first section is a reprint of an address delivered in 1920 when he described the two-stage operation he had devised for making an opening into the external semicircular canal and a covering skin flap. The number of cases treated in this way was small and the results are not given clearly enough for any estimate to be made of the value of the procedures. An extended reprint follows of a report reviewing the work of earlier otologists presented in 1935 to the French Society of Otolaryngologists. Two additions have been made to this report, one written in 1939 and the other in 1947. Inevitably

this method of presentation has led to much repetition but the author covers all the theoretical indications, operation, and the physical factors involved, and gives a possible technique for achieving a patent opening in the labyrinth without infection. The subject is still controversial, and many of the statements made would be endorsed by other workers in the field. Perhaps insufficient credit has been given to Lempert for his original stage operation. The most serious defect is a lack of critical classification and survey of the results obtained.

William Withering of Birmingham

T WHITMORE PECK, K DOUGLAS WILKINSON, Bristol
 John Wright & Sons 1950 Pp 240 21s

THE core of this book is William Withering's great discovery of the therapeutic action of digitalis, and the story is told with many interesting details. At a time when the causes of dropsy were not known and it was not realised that the heart played a part, Withering indicated clearly that success with digitalis can only be hoped for in certain cases—those with a feeble or intermittent pulse, livid lips, and skin—and that "the drug must not be persisted in if the pulse is retarded to an alarming degree." Prof. Wilkinson, who seems to have been responsible for much of the book, has so profound a knowledge of the history of Birmingham in the 18th century that he is able to set the figure of Withering in a background as vivid as it is vivid. Withering, after the manner of his time, was philosopher as well as physician, and it was by the labours of the philosophers that the rapid industrial development of the day was made possible. In the famous Lunar Society at Birmingham the philosopher met to exchange views on literature, art, science, above all the application of science to industry. Withering was on terms more or less familiar with Boulton of Soho, and his partner James Watt, Wedgwood of Etruria, Priestley, Erasmus Darwin, and many others. Dr Wilkinson brings old Birmingham to life again.

Outline of Anaesthesia from the Nurse's Viewpoint (Reprinted from the *Hospital and Social Services Journal* 1950 Pp 24 1s 6d)—Sometime in her career, every nurse is bound to come in contact with an anaesthetised patient. Dr C Langton Hower's booklet sketches in sufficient historical, theoretical, and practical background to enable her to look after such a patient with interest and intelligence.

ese criticisms, the staff seem to have adjusted themselves satisfactorily to the new regime. Only 3% had criticism of new superior appointments under the scheme.

All who take the task of hospital administration naturally will be well advised to read this report in detail, and to see how far the cap fits in their particular institution. "The seniors get soup and coffee for the same price as we pay," says an assistant nurse, "and we aren't even allowed to pay extra to buy them."

"If there is a system of promotion, no one knows about it, I suspect some fiddling goes on."

Night nurses should get a breakfast type of meal in the morning.

"Male nurses should only be answerable to male charge nurses, sisters treat men like little girls—it's bad." This is a hospital coming to life on paper, with the petty irritants exposed to view. Perhaps a time will come when social accounting in hospital life will be no less important than financial accounting, and trained personnel officers will be part of the establishment. But of course it would be easy to carry this sort of thing too far.

Laryngeal Vertigo

SINCE CHARCOT¹ first described a syndrome of sudden unconsciousness during a coughing-attack, interest in the condition has waxed and waned in an odd way. Probably because CHARCOT called it laryngeal vertigo, thereby linking it with the throat, the physician, especially the chest physician who sees the bulk of the cases, often looks on it as outside his province and is relatively ill-informed on the subject. This is a pity, for it is not uncommon, it has a good prognosis, and its mode of production is a worthy theme for speculation. BAKER,² who has collected 9 cases from the records of Guy's Hospital over eight years, and has analysed the published data, builds up a composite picture of the patient. He is a middle-aged man (there were only 6 females among the 177 cases analysed), over-weight and often obese, and, as might be expected from his build, "does himself pretty well", in fact, the attacks often occur while the patient is enjoying company and alcohol. Naturally enough, he combines self-indulgence at the table and the bar with a heavy use of tobacco. By the time he sees the doctor he has a chronic cough and is emphysematous and plethoric but, curiously enough, rarely hypertensive or arteriosclerotic (Possibly those with associated cardiovascular disease do not live long enough to develop Charcot's syndrome.) His voice is as rough and loud as his frequent laugh, for laughter comes easily in the surroundings where he is usually found. He becomes subject to minor or major attacks of laryngeal vertigo. The major attacks, which are more readily recognised than the minor, typically begin as a tickle or irritation in the throat, followed by peculiar irritating coughs which increase in violence until, with suffused congested features, the man falls unconscious. The unconsciousness rarely lasts as long as a minute and is usually over in a few seconds. He then gets up, pale but apparently quite composed and otherwise normal, and continues his activities from where they were dramatically interrupted. He is never incontinent and does not bite his tongue, but he may injure himself by his sudden fall. Minor attacks begin in the same way, but do not go on to

unconsciousness. They cause an odd sensation of giddiness without any loss of equilibrium.

CHARCOT's name for the syndrome was justified, but the emphasis on the larynx and the giddiness has obscured the more disturbing symptom of abrupt loss of consciousness. This sign of cerebral involvement, suggestive of a serious organic lesion, gives a special significance to the prognosis and hence to the mechanism of the curious sequence of events. BAKER reviews the known facts and the various theories built on them. One view is that this is a form of epilepsy and the attacks arise as a primary cerebral disturbance. But only 4 of the 177 patients were known to have any previous personal or family history of epilepsy, neither the nature of the attacks nor the type of person who gets them is in favour of epilepsy, and lastly, all 3 of ROOK's³ cases had normal encephalograms, which is strong though not conclusive evidence against epilepsy. CHARCOT originally postulated that the attacks were initiated reflexly from the larynx, though he later⁴ admitted that in 2 of his 4 cases he could not find any laryngeal lesion. However, nearly all hearty middle-aged men have some degree of chronic laryngitis, and if this irritation, or the disturbance of intralaryngeal manipulations, could cause reflex cerebral activity and lead to the syndrome one would expect laryngeal vertigo to be much more common. Some of the early cases might have been examples of the carotid sinus syndrome, but this is not associated with coughing and occurs in a more diverse group of people. Most of the later reports of laryngeal vertigo mention that pressure on the carotid sinus did not produce an attack.

Cough is the common factor in nearly all the recorded cases and underlies the production of the attacks. Some of these coughing fits culminate in spasm of the laryngeal muscles, and it has been suggested that this is the essential event and leads to cerebral vascular changes which cause the dizziness and loss of consciousness. An analogy can be drawn with similar occurrences in whooping-cough which have always been presumed to be vascular in origin. A peculiar form of cough seems to be necessary to induce the glottic spasm—a hard jerky series of unproductive coughs against a closed glottis, leading to an uncontrollable bout which ends in dizziness or unconsciousness. The immediate effect of the coughing is to raise the intrapleural pressure and obstruct the venous return through the superior and inferior venæ cavae. This is shown by the suffusion of face and neck which occurs early in the attack. Cerebral congestion may produce dizziness and mental confusion, though rarely, it seems, unconsciousness. Prolongation of the raised intrapleural pressure reduces the filling of the left ventricle and hence causes a fall in cardiac output and blood-pressure. Cerebral anoxæmia follows and is probably the reason for the loss of consciousness, as in Stokes-Adams attacks. The sequence of events is intensified when the lung tissue has lost a considerable amount of its elasticity and when the chest is fixed, as in emphysema, for a rise in intrapulmonary pressure is then more easily transferred to the intrapleural pressure. Thus the predominance of males is explicable, since men are more addicted to tobacco and alcohol which irritate the larynx and lead to chronic

counting helps to reduce the total error still further. The first attempt, by LAGERCRANTZ,⁵ was of little clinical use because the mean diameter of the cells had to be known before the result could be calculated. But now WOLFF⁶ at Oxford reports that he has overcome this difficulty. His counter, the details of which are not yet published, has a special chamber moved mechanically so that a microscope objective fixed above it scans a number of parallel lines. An important feature of the machine is the provision of special stops in the back focal plane of the objective which determine the width of the scanning. The light transmitted through the stops falls on a photo multiplier, and the signals passed on are amplified and mechanically recorded. WOLFF claims a coefficient of variation of 2.1%, so if the machine gives a count of 5,000,000 there is a 20 to 1 chance that the actual number of red cells is between 4,790,000 and 5,210,000 per c mm, or if the count is 2,000,000 that the number per c mm is between 1,920,000 and 2,080,000. This accuracy would satisfy both the statistician and the clinician. If the counter turns out to be robust, reliable, and not too expensive, it will soon be part of standard equipment, and when it is used as a routine the red-cell count and colour-index will regain—thus time justly—their former prestige.

The Happy Ship

Most people who have worked in, or visited, a representative sample of hospitals will agree that their morale varies widely, like that of ships at sea. In the Navy, the happiness or unhappiness of a ship usually depends on the commanding officer. In a hospital, good or bad, is infectious. But the leader of a hospital is nowadays hard to identify. Is it the medical superintendent, where he remains? He will almost certainly say that leadership has passed from him, that what authority he once enjoyed has been whittled away, that the senior medical staff can by-pass him since they are in contract with the regional board, that the senior lay administrator receives communications direct from Ministry and region, which he shows to the superintendent at his discretion. Is it the lay administrator? Some of those least fit to lead will certainly reply that it is their right and duty to do so, while the more modest and perhaps more efficient will explain the difficulties of divided authority. Is it the chairman of the medical committee, or the chairman of the management committee? The former is at best only advisory outside his narrow clinical sphere. The latter, dependent on his officers, and a spare time hospital visitor only, cannot know the true inwardness of hospital life.

So it comes about that many hospitals are now less happy than they should be. Morale is faulty because the new hospital democracy, modelled on that of the voluntary hospitals, has not yet found the institutional traditions which provide an alternative to authoritarian direction. When chiefs are unsure of themselves, or when tyrants are given their head, anxiety and bullying swiftly spread down the chain. Trifling injustices get magnified into tragedies, and there is no universally recognised code of behaviour under which to take shelter. Though a

wise outsider can often identify the point at which a personality defect is throwing things out of joint, the remedy, which must often be dismissal, is usually impossible to apply. Nevertheless, on the other side of the picture, there are in any large organisation a great many points where the application of oil will alleviate unhappiness, and it is good to see a start being made in the study of these friction points. The department of social science of the University of Liverpool has made a survey of employment relations in the Central Wirral Hospital Group, which, as we have already noted,¹ has now been published by the hospital administrators' own professional body.² It is greatly to the credit of the committee, secretary, and staff of the Central Wirral group that they have been not only ready but anxious to submit themselves to the impartial scrutiny of outsiders.

A quarter of the entire staff of the group (numbering 938) was interviewed on a random sampling basis. Some 31 questions were asked, ranging from "Do you like your work?" to "What are your views on the National Health Service, particularly in relation to your work?" Of those interviewed, 87% felt that their hospital was a happy place in which to work, 9% thought it was not, and 4% were doubtful. Every one of the 9% was employed in one of the two largest hospitals in the group, and there were comparatively more feelings of dissatisfaction about every aspect of employment at these larger hospitals. When we consider optimum hospital size, it is worth remembering that the smaller the hospital, the higher appears to be the morale. When asked what changes they would like to see, the staff proposed alterations which are classified as follows:

Joint consultation	84%
Catering facilities	40%
Amenities and services	40%
Conditions of work	33%
Promotion	15%
Wages	13%
Discipline	9%
Relations with supervisor	7%
Training	5%
Facilities for patients	3%

On specific subjects, the highest levels of dissatisfaction were catering 42%, promotion 41%, recreation 32%, and discipline 23%, while the figure for dislike of actual work was the lowest—only 5%. When asked why they took up hospital work, 72% of nurses said it was because they were interested in hospital work, 13% said that it was the best job available, and 1% mentioned a desire to serve the community. (No fewer than 13% of the administrative workers mentioned a desire of this kind.) Criticisms of the National Health Service came largely from those who deplored the passing of the voluntary hospitals. "Our friends should make collections for us again." "the pay bed system should be restored." "they treat the nurses like dirt now."

"patients are now out for all they can get." "there are too many lay committees poking around." It would be true to say that these are prestige criticisms, and "job prestige," particularly for humbler folk, is a vitally important matter. Apart from

These doctors had settled, not in areas where doctors were overworked, but in areas where patients were already too few to provide a reasonable income to the practitioners established there. Furthermore, "it is not fair to the young men who are at the moment in our universities that in this transitional period the country should be flooded with doctors, so that when they are qualified in the near future there will not be a single area where they will be able to find a sphere of work for themselves." Mr. Quin insisted that the aim of the Bill was, not to establish a "closed shop," but to relieve a temporary standstill during which a scheme for redistributing the general medical services could be worked out. That recent developments have told hard on some doctors was testified by Mr. W. M. Wilton. He told of a district with 300 houses where a doctor has been practising for some time. Within the past few months two other doctors have arrived from another part of the country and set up practice beside him. "The result is that there is not a living for any of them."

Professor Corkey observed in the debate that in the Act of 1948 the aim had been to preserve the doctor's liberty to practise where he would. This liberty, it seems, can be as damaging to the profession itself as to any other group, and the medical negotiators will probably agree that restrictions should be imposed, in order to protect those whose livelihoods are threatened.

A NEW LEAGUE AGAINST EPILEPSY

"ABOUT epileptics," the late Dr. Tylor Fox wrote in 1947, "it may indeed be said that only knowledge of the truth will set them free."¹ Throughout his life, much of which was spent in the care of epileptics at Lingfield Colony, he was constantly teaching the truth about epilepsy—that it is a symptom only, and that because they have this one manifestation in common, a large and varied group of people are classed together. Ignorance and prejudice ascribe other characteristics to the group as a whole, and thus increase the social handicap under which those with epilepsy suffer. Dr. Fox's wish to see people better informed about epilepsy went very deep, and he wrote much on the subject. He thought very well of the American leagues of lay people² which use articles, lectures, and broadcasts to spread enlightenment.

On July 7 a group of interested people met to form a British league of like kind, with which his name is to be associated as a memorial. Lady Cynthia Colville, who presided, suggested that the aims of such a league must be to create a proper understanding of epilepsy in the public, to establish an information and advisory service, first in London and then at centres all over the country, to set up hostels and convalescent homes for those with epilepsy, and to publish for them accounts of recent developments in the study or treatment of the condition. Dr. Macdonald Critchley suggested that the American leagues might well be able to supply useful experience, and undertook to find out more about them. Dr. Letitia Fairfield spoke of the revolution brought about in our understanding of epilepsy by the electroencephalograph, and the difference in alertness and physical well-being which modern methods of treatment have made to patients. But they are still excluded from most convalescent homes, they still have difficulty in finding employment, and they are expressly excluded by many voluntary societies from their activities.

Dr. Russell Brain paid great tribute to Dr. Fox as a humanist as well as a doctor. For scientists, as Dr. Dennis Williams said, epilepsy offers a means of studying the function of the brain: their researches must ultimately benefit those with epilepsy, but their aim is not primarily the care of individual people. That is a task for a lay society, which should, he thinks, be concerned particularly for the otherwise normal person with

epilepsy. Physicians, he suggested, should not be invited to be members, but should be merely advisory. Mr. Maguire, lay superintendent of St. David's Hospital, has the charge of 200 epileptic men and boys over the age of sixteen. He was able to describe from first-hand knowledge how people with epilepsy are penalised in the labour market because of their symptom. There is some reason for it: industrialists find that when an employee has a fit the rest stop work and gather round, and he has been shown figures demonstrating how much it costs the firm every time a man has a fit. Mr. Blackshaw remarked that, as a schoolmaster, he had had much the same trouble over the epileptic child. These difficulties are a good measure of the need for education: school masters and then children, employers, and then employees, must learn to take a fit as casually as the person who has had it does (if he is allowed) in retrospect. Dr. W. S. Maclay drew attention to the ruling of the Ministry of Health that epileptics are not "sick" people, or rather that they may be sick epileptics or well epileptics. This has advantages, for if they are held to be sick they cannot be registered under the Disabled Persons Act.

The league was formed by unanimous consent. Miss Irene Gardner, who has been secretary of the working party planning the league, agreed to continue in office, and Lady Cynthia Colville consented to go on acting as chairman. A provisional council was appointed, and a subscription of a guinea for complete membership was agreed on. The league has been formed under the auspices, but independently, of the National Association for Mental Health, and is receiving encouragement and support from the British branch of the International League Against Epilepsy. It deserves great success.

ANTIBIOTICS IN THE U.S.A.

SINCE deep tank fermentation replaced flask cultivation as the routine large scale method of preparing penicillin, there has been a rapid and continuous increase in the demand for antibiotics. Their manufacture has now become one of the major chemical industries in the United States, where, according to J. E. McKeen,¹ it is estimated that some 80% of the world supplies are now prepared. At least 13 firms, he says, manufacture penicillin and 17 make one or more therapeutic agents by aerobic fermentation. When streptomycin was first prepared commercially in 1946, 1132 kg. was produced; three years later the figure had risen to 83,699 kg. It is calculated that 30% of the cases passing through a doctor's hands can be treated with antibiotics, and in 1948 almost half the drug bill of New York department

of hospitals was for penicillin and streptomycin. Research continues not only to develop antibiotics which will be active against recalcitrant diseases, but also to increase the range of those that are effective when taken orally.

McKeen, who is president of Chas. Pfizer & Co., Inc., gives the above figures to show the expansion of American production of "ethical" drugs—i.e., those not advertised to the public—in recent years. They are in millions of dollars.

cough, they cough more vigorously, and they are more liable to emphysema and rigid chests. The cerebral anaemia is relieved immediately the intrapleural pressure drops, and this occurs when the coughing attack ceases, which it does automatically as soon as the patient loses consciousness. Thus the loss of consciousness leads to its own recovery by a fortuitous cycle of events, and this view is supported by the fact that only 2 fatal cases have been recorded. Treatment is simple, the avoidance of respiratory irritants being the most important. Correct diagnosis is therefore all important, and once it is established there is little cause for alarm.

Annotations

ACTION ON TUBERCULOSIS

LAST week a Scottish committee called for a "crisis expansion" of the tuberculosis service.¹ Further welcome evidence of a new effort to cope with the disease now comes from the Ministry of Health,² which points out that "many more beds must be made available quickly, without waiting on progress in making good the lack of staff which is a major cause of the present shortage of accommodation." The Minister, deeming it necessary that a proportion of beds in general hospitals should be used for tuberculosis, now "asks regional hospital boards and boards of governors to apportion for the admission of respiratory tuberculosis patients as many beds as reasonably possible in suitable general hospitals," and also suggests that boards should consider how far they can use beds in isolation hospitals for the same purpose. He does not specify what proportion of beds should be allocated to tuberculosis; he has said that "there can be no set rule about this."³ But the figure of 10% has been mentioned, and obviously there will be objections from some of the boards, which will have to exclude other patients if they are to clear the separate wards they are now expected to provide. We must hope, however, that any necessary pressure will be exerted, and as a first step the Minister proposes "to invite reports from boards in due course about the arrangements they have been able to make in these matters."

The use of beds in this way should, he says, be limited as far as possible to recoverable cases, and "there should be a check on any tendency to retain patients in institutions longer than is justifiable." He suggests that boards should make themselves familiar with the scheme in action at the Central Middlesex Hospital and the Willesden chest clinic, which combines rest and collapse therapy in the home with short periods of inpatient treatment. "A high standard of clinical judgment is necessary to avoid recommendation of institutional treatment for cases in which it is not essential and for which domiciliary care would suffice," and selection at this stage should aim at using the special treatment available in institutions for those best able to benefit from it.

"Every effort should be made to discover active tuberculosis at the earliest stage and to give the closest attention to contacts and the ascertainment among them of non-reactors to tuberculin with a view to raising their immunity by B.C.G. vaccination. Chest physicians will recognise that it is important to concern themselves no less with prevention and aftercare than with their clinical work, and that it is necessary to give sedulous attention to case finding and the supervision of the tuberculous family, including visitation in the home. The occupational settlement of the tuberculous is part of their aftercare. It needs to be closely co-ordinated with the treatment of the individual case and, therefore, to be no less the concern of the chest physician than the clinical management of the case."

Though primarily addressing the hospital authorities—without whose vigorous action the present deplorable

situation cannot be remedied—the Minister drew attention to the responsibilities of local health authorities, and to the important part to be played by general practitioners in the campaign. His memorandum the signal, so long awaited, for the regrouping of forces without which tuberculosis will continue to infiltrate our defences and destroy so many homes. Without going beyond "the limitations which the need for economy imposes" our resistance can, by joint endeavour, be made more equal to the attack.

OPPOSITION TO A HEALTH CENTRE

THE Government's ban on building has been generally accepted as a reason for not having health centres, and many people talk as though the creation of such centres depended purely on bricks and mortar. Actually the immaterial problems may at first prove just as intractable as the material ones—which is one of the reasons why experimental centres should be set up in various parts of the country without further delay, even if the buildings fall short of the optimum. A sharp reminder that something more than a suitable building is needed if a centre is to flourish has come from Sheffield. There, at Firth Park, the opening of a centre is being delayed because, it seems, of the reluctance of the doctors who intended to work there to do so against the wishes of their neighbours. Both the executive council and the city council are unwilling to abandon the project, and the matter has now been referred to the Minister of Health. If it were decided later to advertise for doctors to staff the centre, this would worsen the position; it would be better for the local doctors to accept the entry of their colleagues into the centre rather than have new doctors imported from elsewhere. To import new doctors would be hardly fair to those who have stood back, and it certainly would not augur well for the success of the scheme.

Difficulties of this sort were foreseen, and awareness of them underlies the decision to limit, in general, the construction of centres to areas where the population is growing. But it is a daunting thought that, supposing the building resources were there, centres could be developed only as quickly as the population was rehoused. For the places where they are most needed are the centres of our industrial areas—such as Sheffield.

PRACTICE IN NORTHERN IRELAND

THE Health Services (Temporary Provisions) Bill, which last week was read a second time in the Northern Ireland Senate, owes its origin largely to the fact that the Health Services Act of 1948, unlike the National Health Service Acts of England and Wales and of Scotland, contains no provision for regulating the entry of doctors into general practice. Thus, while thickly populated industrial areas are no less underdoctored than before, more attractive districts are rapidly becoming overcrowded with doctors. The effect of the Bill will be to prevent new practitioners, except those already in assistantships, from beginning to take patients. The measure is to be effective for only six months, during which the ministry of health and local government will seek to work out a solution with the medical profession.

In the Senate debate, Prof. R. Corkey remarked that Northern Ireland has more doctors per thousand of the population than any other part of the United Kingdom. Since the Act of 1948 came into operation, an unprecedented number of new doctors had entered the country. In the past the number required to replace wastage was between 10 and 20 per annum, yet in the twelve months up to March 31 no fewer than 48 new doctors had entered the services of the General Health Services Board, and in the three months since then a further 22 had demanded places among the "panel doctors."

³ *Lancet* July 8 1950 p. 70

board itself, rather than to a multiplicity of management committees. Organisation along such lines may well provide the answer to problems now facing all regions in the development of their service in pathology.

ACCESS TO THE SERVICE

The facilities of the National Health Service in pathology must be as freely available to patients under treatment by their own general practitioners as to those in, or attending, hospital. Time was when the only means of access open to the general practitioner wishing to obtain the opinion of the pathologist on his patients lay through one of the medical or surgical outpatient clinics of the hospital. Before the appointed day an increasing number of the (then) voluntary hospitals had made it possible for practitioners to refer their patients directly to the pathological departments, but there were still many hospitals in which no such provision was made. Reluctance to permit general practitioners direct access to the pathological department was to be found both on the part of certain pathologists and also of their medical and surgical colleagues.

A considerable change has been wrought in the climate of opinion by the National Health Service Act and it is now accepted that the services of the pathologist and his department must be freely open to all practitioners working under the Act and not to members of the hospital staff only, this is the "open door," demanded by National Health Insurance practitioners for many years past.

The adoption of this principle makes it necessary that hospital laboratories should be provided with waiting rooms and accommodation for the examination of patients and the collection of specimens of all sorts. Few of the laboratories of the old voluntary hospitals and fewer still of the municipal hospitals possessed such facilities. It will be the concern of regional boards and hospital management committees to see that such accommodation is provided as expeditiously as possible, in the meantime a great deal can be and is already being done by improvisation.

EXCESSIVE DEMANDS ON THE SERVICE

There are those who fear that the provision of facilities for pathological investigations for all patients under the National Health Service, in and out of hospital alike, will lead to a vast increase in the number of laboratory investigations, many to no useful end. They point out that already many hospital laboratories are overwhelmed by the requests for examination on patients actually under hospital treatment. It is customary to blame this increase of useless investigations upon the junior house staff and it is not unusual to hear senior clinicians attributing the decay of clinical sense to the baneful influence of the laboratory, but this is to confuse cause and effect. In the teaching hospitals, according to the testimony of those who have recently left them, less odium is likely to be incurred by demanding of the laboratory half a dozen investigations not really relevant to the case than by omitting to request a single one which may prove even remotely so. It may be that it is not the business of the practitioners of purely clinical medicine to safeguard the pathological department, but it is most emphatically the business of the pathologist to do so and to ensure that its resources are not wastefully expended. Not only that it is also his duty to see that those resources are employed to further clinical practice to the fullest possible extent. To this end the presence of the pathologist is required in the wards both on the rounds of the senior members of the staff and for consultation with any member senior or junior as required, he must also be available for consultation at the bedside of patients under the care of their own practitioners in their own homes.

It is the function of the pathologist to indicate those avenues of approach to clinical problems through the laboratory likely to be of avail, and to interpret the results of the investigations performed in his department in the light of the particular problem in question. He must endeavour to persuade his colleagues that the bald facts and figures stated on his report forms are merely a part of the whole picture presented by the case, and that unless considered as such they are often useless and not uncommonly dangerously misleading.

It is possibly significant that perturbation about the increase in the demands upon the hospital laboratory has found expression mainly among the academic members of the staffs of teaching hospitals. This may be due to a very proper reluctance on the part of those whose main interest is teaching and research to sacrifice these in favour of routine. A similar problem faced the early Church, the solution as set out in *Acts*, vi, 2, is eminently relevant.

The seeds of corruption may lie within the whole organisation set up under the National Health Service Act, if so they will affect the service in pathology along with those in all other branches of medicine and must be dealt with as they begin to appear, but if pathologists themselves play their part there need be no breakdown by reason of unbounded demands.

The major danger threatening the service in pathology is common to the whole hospital service—in fact to the entire set-up under the Act. It lies in the inflexibility of bureaucratic control. There is a growing sense of frustration among pathologists, many of whom initially welcomed the extension of their departments under the Act, and this arises largely from the necessity of doing everything through "proper channels" which even when discovered are likely to be found choked beyond capacity.

None the less this attempt to develop a national service in clinical pathology constitutes one of the most interesting features of the new National Health Service. Nothing of the kind has been attempted in any country other than Great Britain. It is possible to overrate the value of clinical pathology, but it has established its place in the field of medicine and that place must be a large one—how large it is at present difficult to say. Further it is possible to develop clinical pathology along wrong and meretricious lines, it will take time to establish its place in the field of medicine—indeed it may never prove possible to determine that place with exactitude. A standardised practice of clinical pathology, or of any other branch of medicine, is the last thing to be desired. The initiation of the present service must be regarded as an experiment which with proper guidance may provide results of the utmost value to the development of medicine not only in this country but throughout the world.

CENTRAL HEALTH SERVICES COUNCIL

First Report

THE Central Health Services Council and the associated standing committees provide the main professional advisory machinery in the National Health Service. The duty of the council itself is

'to advise the Minister upon such general matters relating to the services provided under this Act or any services provided by local health authorities in their capacity as such authorities as the Council think fit and upon any questions referred to them by him relating to those services.'

In the report¹ on its first eighteen months of work, the council declares that its task is 'not only to consider

PATHOLOGIST, THE ROYAL HOSPITAL, WOLVERHAMPTON

UNDER the National Health Service Act, 1946, we are now bringing into existence—for the first time in this or any other country—a service in clinical pathology, centred upon the national hospitals and designed to bring the pathological laboratory into the closest possible touch with the practice of clinical medicine. The avenue of approach to clinical problems through the pathological laboratory was entirely ignored in the formulation of the National Health Insurance Act, 1911, in the National Health Service Act, 1946, its importance has been fully recognised, and we are now faced with the problem of developing this branch of medical practice so that it may best fill its place in the National Health Service. It is essential that at this early stage we should have some general idea of how the service should be organised, and of its aims and scope.

The organisation of the service in clinical pathology is determined by the fact that it is a part of the national hospital service. Its growth and development must therefore proceed upon the foundation of hospital departments in pathology.

THE REGIONAL HOSPITAL SERVICE

By far the greater part of hospital clinical practice in this country is carried on in what since the "appointed day" have become the regional hospitals, and their pathological departments must be the instruments of the national service in clinical pathology.

It goes without saying that the regional service in pathology, as in all other branches of medicine, must work in the closest possible touch with the university centres. It is essential that the regional workers be alive to the trends, tendencies, and recent advances in their subjects, and it should be a function of university teachers to keep them so. But though all may work in the same spirit there are, as between the academic and the clinical pathologist, differences of administration and diversity of operations.

The aims of the service in clinical pathology must be strictly practical. Its purpose is to give quickly all possible aid in the diagnosis and the control of the treatment of disease. In fulfilling this function, the department will in its routine work, continually present opportunities for observation of the natural history of disease, the alert pathologist in such a department will be in a position to make valuable contributions to medicine, and may be regarded as delinquent if he fails so to do. But organised research into problems not immediately related to the clinical practice of medicine are the sphere of university departments and of institutions devoted to and organised for that purpose. It is an error to suppose that every regional hospital department of pathology must be a replica of the university or research department, and the attempt to organise them as such can only lead to waste of effort, personnel, and material alike.

TECHNICAL STAFF

Clinical pathology is a rapidly expanding field, how rapid its expansion has been only those who have worked in it for the last quarter of a century can fully realise. The central portion of the field has been thoroughly cultivated and can largely be left to the care of properly trained technicians working under the supervision of medically trained staff, such trained technicians will

be required in increasing numbers. The periphery of the field is continually expanding, it is in this periphery that new measures are tested and new techniques placed on trial, some of these will in due course be discarded, others will become matters of routine and will be passed into the hands of technical staff, leaving the medically-trained staff free to test and assay new procedures and attempt other lines of approach.

GROUPING OF SERVICES IN PATHOLOGY

Every hospital must have its facilities for pathological investigations but that does not mean that every hospital must have a fully equipped and staffed pathological laboratory. In the 14 hospital regions of England and Wales there are over 350 hospital management committee groups. These groups vary greatly in size, some comprising one or even more than one active general hospital, others having within them no major hospital at all. There is a tendency for every hospital management committee to strive to function as an autonomous unit providing a service in all branches of medicine—pathology included—entirely under its own control. The consultant staff is the responsibility of the regional board, but the lower ranks of the medically qualified and the whole of the technical staff, together with provision of equipment and of accommodation and maintenance of existing buildings, are directly the charge of the hospital management committee. This disposition places the responsible head of a regional hospital department of pathology in the unfortunate position of being answerable to two bodies which may be far from seeing eye to eye with each other. Extreme centralisation is bad but extreme decentralisation is even worse.

FUNCTIONAL AREAS

It is to be hoped that the future may bring some degree of centralisation into the service in pathology. As a step towards this it is essential that it be organised into "functional" areas which in many instances must overlap the boundaries of individual hospital management committees. Pathologists working in any such area may well be based upon a certain hospital in that area, but they should be regarded as members of the area service and as working under the general supervision of one of their number who is recognised by the regional board as the head of the service in pathology of that area. Similarly there should be opportunity for free interchange of technicians working within such a functional area, no matter by what hospital management committee they may be employed. Technicians cannot be liable to arbitrary transfer from one hospital to another, but with their consent, and at the discretion of the head of the service, they may well from time to time and for stated periods be transferred to other laboratories within the area—either for purposes of instruction or to tide over an emergency. Such an arrangement may interfere with administrative convenience, but entails no difficulties which cannot readily be overcome.

Certain classes of work, requiring the use of particularly expensive apparatus or of specially trained staff, should be concentrated in one of the departments within the area. This applies in particular to biochemistry and histology. Only the laboratory of a major hospital can demand the services of a fully trained biochemist, this is essentially one of those appointments which should be made to a functional area, and it would be well that it should be made by a regional authority. Similarly, highly expensive apparatus should only be found in those laboratories where the bulk of work can justify its presence.

At least one region has divided itself for the purpose of certain of its hospital services, pathology among them, into "clinical areas" having within themselves a certain degree of autonomy and oriented towards the regional

APPOINTMENTS

The Minister has lately made the following appointments to the council

Medical practitioners—Dr Janet Aitken, Prof Robert Cruickshank, Sir Stewart Duke-Elder, Dr W V Howells and Dr C W Walker

Persons with experience in hospital management—The Hon A. J. P. Howard and Mr F S Stanchiffe

Persons with experience in local government—Mr A. F. Bradbeer and Mrs Dorothy Thurtle

Dental practitioners—Mr Joseph Lauer and Prof R V Bradlaw F.R.C.S.

Registered nurse—Miss Clare Alexander

The following appointments have been made to standing advisory committees

Medical—Dr Aitken, Professor Cruickshank, Sir Stewart Duke-Elder, Dr Howells and Dr Walker

Dental—Mr C V Armitage and Mr Lauer

Ophthalmic—Dr Aitken and Sir Stewart Duke Elder

Nursing—Miss Alexander, Dr Horace Joules, the Hon A. J. P. Howard, Prof R. M. F. Picken, M.B., and Mr S. Stanchiffe

Maternity and midwifery—Dr Aitken, Mr A. W. Bourne F.R.C.O.G., Dr Howells, Mrs Thurtle, Dr Walker, and Mr W. Onions

Mental health—Dr Denis Williams

Cancer and radiotherapy—Dr Howells

MEDICAL RESEARCH IN SCOTLAND

THE Secretary of State for Scotland has appointed an Advisory Committee on Medical Research in Scotland, to advise the Secretary of State on the 'initiation, direction, co-ordination, and conduct of medical research.' The committee's appointment follows discussions with the principals of the universities, the deans of faculties of medicine, and the presidents of the Royal Scottish Medical Corporations. Besides advising the Secretary of State on research projects and recommending financial aid, the committee will be available to give advice to regional hospital boards, local health authorities, and any other organisation which feels it could benefit by it.

Close contact will be maintained between the committee and the Medical Research Council, representatives of which are included in the committee's membership. The committee will concern itself mainly with investigations that can best be done within the framework of the health services in Scotland. The members are

SIR EDWARD APPLETON, D.Sc., F.R.S. (chairman), Prof THOMAS FERGUSON, professor of public health, Glasgow University (vice-chairman), Prof DUGALD BAIRD, professor of midwifery, Aberdeen University, Dr C. A. BIGG, medical officer of health, Ayr county, Prof NORLAN FEATHER, F.R.S., professor of natural philosophy, Edinburgh University, Prof T. FERGUSON RODGER, professor of psychological medicine, Glasgow University, Prof J. H. GADDUM, F.R.S., professor of materia medica, Edinburgh University, Prof R. C. GAERT, regius professor of physiology, Glasgow University, Prof S. G. GRAHAM, professor of child health, Glasgow University, Dr H. P. HINSWORTH, secretary of the Medical Research Council, Sir JAMES LEARMONTH, professor of surgery and regius professor of clinical surgery, Edinburgh University, Prof J. W. McNEE, regius professor of practice of medicine, Glasgow University, Prof W. J. TULLOCH, professor of bacteriology, St Andrews University, Prof C. H. WADDINGTON, Sc.D., F.R.S., professor of animal genetics, Edinburgh University.

The joint secretaries are Dr F. J. C. HERBOLD, of the Medical Research Council, and Dr J. M. JOHNSTON, of the Department of Health for Scotland. Communications should be sent to Dr Johnston.

At its first meeting on July 4, the committee considered the uncompleted work of various subcommittees of the Scottish Scientific Advisory Committee whose functions are included in the wider remit of the new body. The committee also agreed on procedure and discussed methods of handling new projects.

REABLEMENT IN THE R.A.F.

A PATIENT recovering from an injury should never leave his cure entirely to others. If he wants the job done properly he must do a good deal of it himself. This principle is so well understood at the new R.A.F. Medical Rehabilitation Unit at Headley Court, Surrey, that a newcomer is at once invited to join a team of four bent on getting him fit again: the other members being the medical officer, the physical fitness officer (trained in remedial exercises), and the physiotherapist. The medical officer takes a full case history, examines the patient and works out a remedial programme for him; the physical fitness officer and the physiotherapist help him to carry it out, and the medical officer checks his progress week by week.

THE PATIENT AT HIS EXERCISE

His working day lasts from 9.15 A.M. to 4.30 P.M. and is mapped into half-hour periods. Under the physical fitness officer are eight physical training instructors who have been trained at the older unit at Collaton Cross, near Plymouth, and know all about the reablement of individual muscle groups. At least one of them has his own muscles under such control that he appears to be able to twitch each one separately, and can ripple and shrug his abdominal wall in a way which would be the envy and despair of an Egyptian dancer. Under these experts the patient begins his day with limbering-up exercises followed by physical training and games chosen to suit his special disability; in the afternoon there is more physical training, somewhat more interesting games, and a period called 'instructor's choice' when a class may challenge another class to water polo, play french cricket, take a cross-country run, do some gardening, or undertake some other diversion which offers the appropriate exercise but adds variety as a sauce to this usual dish.

Patients begin in a small class and graduate to larger ones. On admission they are grouped according to their injuries—quadriceps, legs, arms, spines (including posture) and so on. These groups are split up into smaller classes according to the muscles and joints affected, and the classes are given separate instruction but also combine at times for training with the group. Since exercises are apt to become tedious, each is accompanied by its own theme song, and heard from a distance the songs sound very well. As weak muscles gain power, patients graduate into larger and larger groups until they reach the mobile groups and are classed simply into "upper halves" and "lower halves." The upper-half group, recovering from arm and shoulder injuries or indeed any injuries above the waist, can undertake longer runs and more violent exertion with the legs than the lower-half group, whose injuries were below the waist, but otherwise patients who have reached the mobile grade are expected to be equal to very strenuous exercises. The standard is exacting and when they finally leave is far above anything the ordinary man calls fit. According to the physical fitness officer it takes them about a year to get over it.

In and out of this basic programme of physical training, the essence of reablement, are fitted sessions with the physiotherapist. Much of the apparatus was designed and made by a "Technical Repair and Development" section of the R.A.F. Electronic stimulators have been designed to give maximum muscle response with minimum skin stimulation. Many of the machines are prototypes. Occupational therapy also has its place in the programme, beautifully finished looms and other equipment are now in action. Heavier work will be done in the carpenter's shop. Games, swimming and archery fill in odd moments.

specific requests for advice from the Minister, but to review the general development of the Health Service and to study any matter to which, in our opinion, the Minister's attention should be called," limiting itself, however, to matters of broad general policy, and excluding matters for which other machinery has been established. The council insists that it is a body of confidential advisers to the Minister, all members serving as individuals and none as delegates. In the main, the advice submitted will be published only in the statutory annual report. "This does not, however, prevent us from suggesting to the Minister that reports on special subjects might be published or that press notices might be issued announcing that we are undertaking particular lines of enquiry."

The Ministry proposed that there should be ten standing advisory committees—medical, dental, pharmaceutical, ophthalmic, nursing, maternity and midwifery, mental health, tuberculosis, cancer and radiotherapy, and child health. The council agreed with this proposal, except that it decided to defer setting up a special committee on child health until the problems in this field were more clearly defined.

Discussion of the constitution of these committees occupied many months, owing to a difference of opinion as to whether their membership should be exclusively professional.

The debate soon centred round the question whether the Medical, Dental, Pharmaceutical and Ophthalmic Committees should or should not include lay members with local authority, executive council or hospital experience. This was an issue on which we ourselves were sharply divided, and when a vote was taken on the membership of the Medical Committee, considered as a test case, only a narrow majority of us was prepared to advise the Minister that the Committee should contain a small element of lay representation. When our recommendations following this vote were made to the Minister, he was not able to accept them. He considered that he should normally be able to look to these four Committees for purely technical advice and that questions affecting the Medical, Pharmaceutical, Dental and Ophthalmic services as a whole should be discussed in full Council or in special Committees of the Council. We therefore acquiesced, although two of our members felt it necessary to register their dissent.

The first advisory committee met on Feb. 28, 1949, and by April 29 all had held their first meeting. The council's relation to these committees is probably without parallel.

The committees are independent statutory bodies which may submit advice direct to the Minister, if they do so, they must send copies of their report to the council, which may express its views thereon. Normally the committees receive their remits direct from the Minister, and then they report direct to the Minister. Where the report deals with issues beyond the service with which the particular committee is concerned, the council normally expresses its view and forwards this to the Minister. The Minister has undertaken not to act, except in an emergency, on the report of any standing advisory committee before the council has had a chance to express its views.

The committees can also act as if they were committees of the council, and the council can remit matters to them, in this event the report must be sent back to the council. A Committee may, of its own volition, send a particular report to the council rather than to the Minister if it feels that the council may wish to consider its wider implications.

Thus "it has been accepted that the Council should act as a pivot for all the Committees, that it should ensure that similar procedures are adopted throughout, and that there is due co-ordination between the work of the Committees, so that the central advisory system of the National Health Service works as a whole and not as a number of disjointed parts offering unrelated advice to the Minister."

THE COUNCIL'S WORK

The council met first on July 27, 1948, and the Minister of Health, in a statement published with the

report, remarks that since then he has remitted some thirty questions for consideration by the council and the Committees, while these bodies have volunteered advice on more than a dozen further matters. Many of these reports have already been acted on.

Health Centres—The council's committee on health centres, "realises that for some time the economic condition of the country will make it impracticable for there to be any widespread provision of health centres with accommodation, equipment and staff of ideal standard." It proposes, therefore, to include in its report (which will be concerned only with centres in urban areas) a section giving practical advice on what could be done now, including particulars of the minimum requirements of types of health centres which could be provided notwithstanding present circumstances. The committee recommended that doctors practising at health centres should be permitted to treat private patients there, and effect was given to this recommendation in the schedule to the amending Act of 1949.

Hospital Administration—In December, 1949, the council's committee on hospital administration advised the Minister that he should "invite the King Edward's Fund and the Nuffield Trust to undertake a complete unit costing of a small number of representative London and Provincial hospitals." This recommendation has been accepted, and these two bodies have been approached.

Prescribing—A joint subcommittee of the councils for England and Wales and for Scotland have reviewed a large number of substances, classifying them according to whether they were primarily foods or medicines, the aim being, in general, to eliminate prescription, under the service, of substances which are primarily nutritional. This committee is now considering toilet preparations, disinfectants, and antiseptics. Another joint subcommittee has reviewed the desirability of restricting the prescription of preparations which are extremely expensive or of doubtful value.

Pressure on the Hospitals—In the summer of 1949 the Minister was advised that an emergency bed bureau should be set up for each appropriate area, and this is now being done.

Integration—Referring to coordination between the various branches of whole service, the council remarks that the time has come when this problem "should be considered as a whole and not in relation to separate services. We have therefore asked the other committees concerned not to submit any advice to the Minister on this matter for the present and we propose to consider during 1950 what advice should be formulated on this subject."

ADVISORY COMMITTEES

Medical—This committee has been mainly preoccupied with problems of hospital congestion, the treatment of the elderly chronic sick, and prescribing.

Dental—The standing dental advisory committee has advised the Minister that the extension of training facilities for chairside assistants should be encouraged. It has also accepted the Minister's invitation to cooperate in assessing the results of the experiment which has been begun in the training of oral hygienists, and a mission has visited New Zealand to obtain first hand information about the work and training of dental nurses in that country.

Nursing—This committee has laid down criteria for the employment of young persons in hospitals.

The views of these and other advisory committees have been reflected in directives issued from time to time by the Ministry.

first see the place. The Station Headquarters is another separate building adjoining the medical block.

The living quarters of the A.C.O.s and airmen staff, and A.C.O. patients, lying across the road from the main gates of the unit, must provide another shock. The R.A.F.-blue corridors are lined with small dormitories where each of the three or four well sprung beds has its own head light, and every man has his

Instruction in archery

wardrobe locker, with shelves, hanging space, and mirror. Some of these quarters were designed for W.R.A.F. (who are not, unfortunately, to enjoy the advantages of them), and the men who occupy these rooms get the

added refinement of a long mirror each and modestly private bathrooms.

The dining rooms have stout plain tables and beautifully made wooden chairs designed to stand hard wear and yet to please the eye. The kitchens have every modern device, far beyond any housewife's hopes in this age and country. The charming window curtains differ in every block, and like the slight but lively decorations, can hardly fail to have their own effect on health and spirits. The sergeants have better quarters than the airmen, and the officers better quarters than either, after the well established Service tradition, but when all is so good there is very little in it.

A mood of comradeship, well being, and enthusiasm for "getting better" is part of the place. It began during the darkest days of the war, at the Rehabilitation Centre at Loughborough, and was handed on to Mongewell Park, which has now closed down. Most of the staff and original patients of Headley Court came from Mongewell, and they brought this spirit with them. The R.A.F. have a well founded reputation for liking the best of everything and seeing that they get it. The new unit conforms handsomely to this oldest custom of the youngest Service.

Public Health

Poliomyelitis

NOTIFICATIONS of poliomyelitis in the week ended July 1 numbered paralytic cases 124 (104), nonparalytic cases 36 (38). Figures for the previous week are shown in parentheses. There has been a small rise in notifications in the country as a whole, but the main centre of high prevalence is still in the Birmingham region. This year the disease seems to be following the epidemiological pattern of 1938 rather than that of 1947 or 1949.

Composition of Ice-cream

The Food Standards Committee has proposed an interim standard of composition for ice-cream of 5% fat, 10% sugar, and 7½% milk solids other than fat. The committee maintains that the standard should be progressively improved as ingredients become more plentiful, and that in the long term the description "ice-cream" should be restricted to a dairy preparation containing a high proportion of milk solids.

School Medicine in France

In 1793 a decree of the new Republic of France contained the germ of a school medical service, but it was not until an order made in 1837, under a law of 1836, that much growth came from it. This order prescribed the provision of medical inspectors for public and private schools, whose duties were to survey the health of the children—"La salubrité des locaux et l'observation des règles de l'hygiène scolaire." This can be compared with our Educational Provisions Act of 1907 which introduced school medical inspection and established school medicine in Britain as a State function.

The growth of school medicine was different in the two countries owing to the difference in their systems of local government. In France the local authorities and towns have much greater powers than our county and borough councils in deciding what laws and orders of the central government they will enforce. In consequence, the practice of school medicine and of public health developed unevenly in the various units. In 1930 a study-group of the Health Organisation of the League of Nations visited France to explore public-health administration, in some districts this was as complete as it could be, while in others it scarcely existed.

In 1945 the practice of school medicine was made obligatory, and its principles were defined on a national basis. From then until 1948 the practice of school

medicine in France was in most respects similar to that in Britain, but it was in advance of British practice in that the school doctors were concerned with the health of teachers, and had much better means of controlling tuberculosis, and the Académie Nationale de Médecine was entrusted with the working of the service and with the supply of personnel, or at least its approval. By a decree of September, 1948, the powers of the Academy were withdrawn, and—apparently in the interests of national economy—administration of the service reverted to the departments.

Considering the difficulties of the times, the results achieved between 1945 and 1948 were highly satisfactory, and Dr. Auguste Robert¹ inspecteur-général honoraire de l'hygiène scolaire et universitaire has spoken for the many doctors and others who wish to see central administration restored. The Commission d'Hygiène de l'Enfance has claimed that the organisation set up between 1945 and 1948 was unequalled throughout the world, and has protested that it was suppressed by a stroke of the pen and without the smallest justification.²

School medicine owes much to France, and it is exasperating for a country which was in the van to be thus hampered.

Training groups in the exercise hall

PURPOSES OF THE UNIT

Though most of those admitted are recovering from injuries, a few have medical conditions.

The official opening by the Duchess of Kent took place on July 3 and the unit is now ready to receive its full complement of 50 officers and 50 air crew N C O s. No distinctions of rank are made in the classes though both the officers and the sergeants have separate messes and living quarters from lower ranks.

The senior medical officer's staff at present includes, besides the officers already mentioned, a welfare officer responsible for occupational therapy, and also for arranging entertainments for the patients (including free tickets

Exercises for individual cases

for London theatres) 5 physiotherapists (3 R A F senior N C O s and 2 civilian women), a radiographer and photographer, a visiting dental officer, a nursing sister with 2 non-commissioned officers and 4 orderlies to help her, and 2 senior N C O s and 2 clerks responsible for administration and stores.

THE SETTING

So much for the people, the quarters in which they work are nearly as remarkable. At the end of the war, the Chartered Auctioneers and Estate Agents Institute decided that they wished to give a reablement centre to the R A F, and collected a fund of £150,000. With this they bought Headley Court, a comfortable solid house, built in 1900 and beautifully fitted in many of the rooms with old panelling taken from ancient houses. This has become the officers' mess for staff and patients. Round it have now been placed a harmonious group of buildings which house the exercise hall, swimming bath, physiotherapy and occupational therapy departments, the administrative offices, the dental surgery, and the X ray room and dark room. All the medical buildings

were the gift of the Chartered Society, while the R A F added the administrative block and the living quarters for the patients. The architect has made all the buildings graceful and unpretentious outside, and gay inside, with colours used cleverly but sparingly for decoration on the light walls. The swimming bath is a charming place, a great flight of broad steps spanning the whole width and leading down to the bottom of the water. Here the poliomyelitis patient, or those with stiffened joints, guided by an instructor can do waterborne exercises by the hour together for the water is kept at 90°F in winter and 80°F in summer. The exercise hall—with panels of glass brick in its walls, beautifully fitted floor, patterned ceiling, semicircular platform, and musicians' gallery—is almost too beautiful for use. The gallery looks down from a second smaller exercise hall on the first floor. Along one side of the main hall runs the physiotherapy

Re education of muscles in the swimming pool.

department, fitted with couches and all the appropriate modern accoutrements, its long wall of windows opening on a terrazzo court used for open air exercises. Two small wards, beautifully equipped, are near it, with beds enough for those who need any special nursing on admission. The occupational therapy department and the carpenter's shop lie at the other end of the block. The medical administrative block, which also houses the dental surgery and the X ray department, is separate from the treatment block, and the two lie parallel to each other in a riotously blooming rose garden from which an alley of fancifully cut yews leads the eye down a gentle slope to an endless stretch of country. No wonder some of the patients are taken aback when they

In the physiotherapy department.

means. This is a very imaginative and enterprising scheme by the local people responsible and I am examining it with great interest.

Medical Distinction Awards

Colonel MALCOLM STODDART-SCOTT asked the Minister how long the committee which dealt with merit awards for medical consultants had been sitting, how many times it had met who was its chairman and the salary or fee he had been paid.—Mr BEVAN replied. The committee was appointed on Dec 23, 1948. It has held 24 meetings. Its chairman is the Lord Moran of Manton. He has received 3000 guineas for the first year's service and will receive 2500 guineas for the second year.

B C G Vaccination

Dr CHARLES HILL asked the Minister how many local health authorities were in possession of adequate supplies of B C G and whether he was satisfied that this method of prevention was being made available on an adequate scale and as rapidly as the paramount necessity of preventing tuberculosis demanded.—Mr BEVAN replied. 116 out of 145 authorities in England and Wales have so far had arrangements approved for B C G vaccination at the discretion of chest physicians. They receive the vaccine as they need it since it cannot be stored. As to the second part of the question I would refer to the reply I gave on June 15 [see *Lancet* June 24 p 1174].

Home Treatment of the Tuberculous

Dr HILL asked the Minister whether he would instruct regional hospital boards to arrange for the home treatment of tuberculous patients for whom there were no sanatorium beds vacant by making available to them in their homes the services of chest specialists, portable X-ray facilities and any other facilities necessary for adequate and continuous treatment.—Mr BEVAN replied. It is part of the normal work of the boards' chest specialists, with the resources of the hospital service available to them, to take part in the home treatment of tuberculous patients.

Efficacy of Disinfectants

Dr HILL asked the Minister if he would consult the Medical Research Council with a view to taking steps to ensure that disinfectants produced by manufacturers satisfied minimum standards of efficacy.—Mr BEVAN replied. I am already in touch with the Medical Research Council but as the hon. Member is aware this is a very difficult and technical subject.

Dr HILL. Will the Minister bear in mind, in any consultation he has that there is a wide difference between the effectiveness of the various disinfectants on the market which is unknown to purchasers and that there is an important public health problem involved.—Mr BEVAN. That is the reason why we have asked the technical authorities to lay down standards, but although this matter has now been pursued for very nearly five years no standards have yet been achieved because of the intricacy of the problem.

Supply of Aural Aids

Replying to questions about delays between the time of testing and the time of issue of hearing aids Mr BEVAN said the waiting period varied much according to individual needs and averages had no meaning. The mechanical genius available in this country had been used to tackle this problem for the first time in English history. Between 80 000 and 90 000 aural aids had already been issued. The limitation was not the mechanical genius of the country because we were producing them from the industry faster than technicians could give them to the patients.

Mr SOMERVILLE HASTINGS. Am I right in assuming that it was the genius of the Post Office engineers which was mainly responsible for this wonderful instrument.—Mr BEVAN. It was the co-operation between the physicians on the one hand and the Post Office engineers on the other that produced this aural aid.

Hospital and Specialist Services

Mr HASTINGS asked the Minister what would be the approximate annual saving to the nation if only whole time

medical officers were employed under Part II (Hospital and Specialist Services) of the National Health Service Act, 1946.—Mr BEVAN replied. I regret that the information is not available.

Mr HASTINGS. Am I right in assuming that there will be a saving of about 20%, and if so will the Minister communicate this to the boards of governors when they are reappointing officers in future.—Mr BEVAN. As I do not know what the figures are, I cannot say whether 20% is accurate or inaccurate.

Mr HASTINGS asked the Minister what steps he took to ensure that part time medical officers engaged under Part II (Hospital and Specialist Services) of the National Health Service Act, 1946, were actually employed for the number of notional half-days for which they were paid.—Mr BEVAN replied. It is the responsibility of hospital boards and committees to see that officers carry out the duties for which they are remunerated.

Mr HASTINGS. Is the Minister aware that some officers are paid for sessions for which they never turn up.—Mr BEVAN. I should like to have information as to that, because it seems to me rather extraordinary.

Dr HILL. Will the Minister resist such general allegations without a shred of evidence being produced in their support.—Mr BEVAN. As I said I should like to see the precise information.

Clinical Assistantships

Mr READER HARRIS asked the Minister if he was aware that regional hospital boards had not yet begun to offer clinical assistantships to general practitioners, and what action he proposed taking.—Mr BEVAN replied. I know that appointments of this kind have been offered where the needs of the service demand it. If the hon. Member has any particular case in mind I shall be glad to hear of it.

Mr HASTINGS. Does the Minister realise how important it is from everybody's point of view to keep general practitioners in close contact with their local hospital.—Mr BEVAN. I am very well aware of that and part of the difficulty is to try to bring about a reconciliation between the conflicting claims of the general practitioner on the one hand and the specialist on the other.

Cortisone

Mr BARNET JANNER asked the Minister whether he was aware that Cortisone had been made available for its first widespread distribution to United States hospitals and whether any action was being contemplated for its use in United Kingdom hospitals.—Mr BEVAN replied. I am aware that the production of cortisone in the United States has been increased. Clinical trials are being conducted in this country by the Medical Research Council and the results of these trials will determine the conditions for which the drug is made available here.

Employment of Epileptics

Mr SOMERVILLE HASTINGS asked the Minister of Labour what provision he had made for the employment of manual and clerical workers who suffered from epilepsy but were otherwise capable of taking their normal part in industry.—Mr GEORGE ISAACS replied. Sufferers from epilepsy, like other handicapped persons, can readily get advice and guidance about their employment difficulties from disablement resettlement officers who have been able by special approach to employers to place a considerable number in suitable employment. To assist in this work explanatory notes about epilepsy have been issued by my department to employers for their information and guidance. A number of the more severe cases have been placed in employment under sheltered conditions in Remploy factories.

Motor-cars for District Nurses

Mr A C MANUEL asked the Secretary of State for Scotland what information he had as to the progress made by the local authorities since they became responsible for the nursing service in the provision of motor-cars for district nurses.—Mr H. McNEIL replied. During 1949 100 additional cars were provided for nurses engaged in home nursing services. Of the 903 nurses so engaged in county areas at the end of 1949 556 had cars at their disposal.

Parliament

Entry to General Practice

Dr A D D BROUGHTON took the opportunity of speaking on the Adjournment, on July 7, to bring to the notice of the House and the Minister of Health the difficulties facing doctors who want to enter general practice as partners or principals. The old method of buying practices, he said, often plunged a young man into debt for twenty years, and the abolition of the sale of practices might have been expected to make it easier for young men and women to enter this important field of medical work. They do, in fact, find comparatively little difficulty in getting assistantships, but most of them, particularly the ambitious ones, after a period of assistantship want the greater security to be gained as a partner or principal.

Vacancies for medical practices are advertised by executive councils, but the advertisements are surprisingly few. In the *British Medical Journal* of July 7, he said, there were only 3 such advertisements. A practice with a list of reasonable size when advertised can attract more than 50 applicants. Thus, men in their thirties, married, and some of them with young families, men who served during the war, with good qualifications and considerable experience, including general practice, find themselves unsuccessful applicants, and after several failures some of them begin to feel a sense of inferiority. The majority, however, blame the executive councils, and claim that 90% of the appointments are "fixed". While Dr Broughton did not share that view, he said he could readily understand a man being driven to believe it.

The difficulties of entering general medical practice by means of executive council appointments are so great that most medical graduates try to enter as partners with established practitioners. But all too often they find themselves up against what Dr Broughton said can only be called a racket. While a principal can no longer sell the goodwill of his practice, there is nothing to prevent him insisting that the partner shall occupy a certain dwelling-house, and no limit is fixed to the price he can charge for it. Thus one doctor who answered an advertisement for a partnership received no reply from the doctor, but a house-agent wrote to say that the partnership was conditional upon the applicant's purchase, as a place of residence, of a small bungalow for £8500. Further, during the first three years of the partnership, additional expenses would have to be incurred to the amount of £2500, making the total £9000. Is it right, Dr Broughton asked, that young men or women wishing to start in general medical practice should be burdened with a debt of that size? Not all doctors are trying to rob new entrants in this manner, but he believes that far too many of them are doing so. We are short of doctors, and particularly of general practitioners, but it is still far more difficult than it should be for men and women to gain a foothold in practice.

Dr BARNETT STROSS found this problem none the less disturbing because the evidence of it may be confined to a very few examples. Even if one such distressing case occurs in a year something should be done to make such things impossible. Seeing that the Minister has paid some £66 million for the goodwill of general medical practices, Members of Parliament never expected that practices would be sold again in the way described. If in a back-handed way a medical practice is to be sold twice that, he suggested, is surely illegal. He quoted section 35 (3) of the Act, which debars the sale of premises used for practice at a price above the fair market price. The same should apply, he thought, to the doctor's dwelling house, for those who have worked in general practice know that it is not only the surgery but the place where one lives which counts.

Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, agreed that, though only a few cases may be affected in the way Dr Broughton had described, the Government's wish is that the opportunities for young men to come into medical practice should be made more, rather than less, plentiful. The

reduction of the maximum number of patients on a doctor's list has encouraged general practitioners to employ extra assistants or bring new partners into their practice. The executive councils have declined to classify different parts of the county as underdoctored or overdoctored areas, thus encouraging newcomers to concentrate their attention on parts of the country where more medical care is needed. They have also done their best to persuade doctors to take on assistant or to enter into partnerships so as to increase the medical services in underdoctored districts. The Medical Practices Committee, in their first report, stated that, in their view, preliminary apprenticeship as an assistant is still the best method of entry into general practice. The Government shares that opinion and has encouraged the appointment of assistants by giving grants. Some increase in the number of assistantships has been seen over the country as a whole. There is much greater opportunity today for entry into general practice by merit, Mr Blenkinsop claimed, than there was under the old system. While there has been criticism of particular appointments, the procedure adopted by the executive councils has on the whole brought little complaint, and has been widely regarded as a desirable method of appointing new practitioners. The building up of new practices is being encouraged by the payment, in many cases, of a basic salary of £300 a year, and by means of the Special Inducement Fund, on which claims can be made by doctors setting up practice in particularly difficult and underdoctored areas.

The Government appreciates, however, that there are still very real difficulties, among them the problem of accommodation, to the young doctor. Sometimes a doctor appointed by an executive council cannot accept the appointment because another doctor has already secured the use of the surgery on the outgoing doctor's premises. If any excessive price is being charged for a house which includes the surgery it is an attempt to evade the provisions of the Act, and should be reported to the Medical Practices Committee. Where the house is separate from the surgery the position is rather more difficult to define. The matter is largely one of professional conduct in which the Government would hope to get the co-operation of the profession itself in insisting that this kind of conduct should be condemned. They would wish to gain the co-operation of the British Medical Association in trying to ensure that this practice should be ended by the voluntary action of the practitioners themselves. It might be rather difficult to interpret the Act in such a way as to cover the ordinary living accommodation of a doctor if it is quite distinct and separate from the surgery. But he is prepared, he said, to examine the matter further. The difficulty some doctors find in taking up practices to which they have been appointed, because of lack of accommodation, is already being discussed with the B.M.A., and he hoped that a way will be found to overcome this trouble. The Government is most anxious to try to help in every way it can to encourage the setting up of additional medical practices.

QUESTION TIME

Mentally Deficient Children

Mr W R S PRESCOTT asked the Minister of Health how many mentally deficient children were awaiting admission to institutions, what were the comparable figures at the same date for 1947, 1948, and 1949, and what steps he was taking to expedite admission.—Mr A. BEVAN replied: Figures in regard to mentally defective children are not separately shown. Within the resources available we are, of course, adding to the accommodation available. I am quite aware of the seriousness of the problem, and if we could make more accommodation available I would be delighted.

Hospital Transport Scheme

Mr SAMUEL STOREY asked the Minister if he had considered the report of the West Manchester Hospital Management Committee upon their transport scheme for industrial workers attending hospital outpatient department, and whether, in view of the saving of man hours to industry achieved, he proposed to extend the experiment to other areas.—Mr BEVAN replied: I am arranging for a report on this scheme to ascertain whether equal savings could be secured by other

Letters to the Editor

THE REGISTRAR'S PLIGHT

SIR.—The "registrar problem," discussed in your leading article of June 24, cannot easily be solved without either unfairness to the registrars or detriment to the hospital services. If the present number of registrars is maintained it is certain that many will be unable to obtain consultant posts, and it is hard to know how they can then be employed usefully and contentedly and without wasting their special training. If as seems likely, the number of registrar posts is drastically reduced, the hospital services will become less efficient. Much of the very necessary work now being done by registrars cannot be done well by less experienced people and a compensatory increase in the number of consultants does not seem likely at present.

The eventual number of registrar posts will probably be estimated by predicting the consultant vacancies likely to be open in the future with allowance for some registrars who drop by the wayside and for others who will eventually go abroad or into the Armed Forces. The smaller number of registrars so arrived at will almost certainly be inadequate for the amount of work that is to be done. The gap could be at least partly filled by taking on as registrars more postgraduate students from abroad, many of whom have hitherto been discouraged by the difficulty of getting work while hospital appointments in this country. There are already many such people in Britain, eager for work and experience and if the jobs were available there could be more. Most of them have commitments or prospects at home, and few would likely remain to compete for consultant vacancies here.

It is time for a planned policy of postgraduate medical training based on the needs of the world community and the contribution which this country in particular can make. The present trend, unfortunately, is to pander to the demand for multiple higher qualifications by organising longer and drier didactic lecture courses as preparation for more and more complex examinations. As similar amenities are now available in the Dominions and elsewhere fewer students are likely in the future to come to Britain for these inducements alone. It is not wholly appreciated here that Britain's greatest single attraction to postgraduate students from less thickly populated countries is the concentration of clinical material to be studied and the vast bulk of work to be done in British hospitals. If this asset can be used to the full in postgraduate teaching Britain's future as a world medical centre will become much more certain. It is to be hoped that the final establishment of registrar posts is not set too low until this possibility has been thoroughly explored and a broad policy decided upon to which the Ministry, the Royal colleges, and the universities could all contribute to their mutual advantage.

Aberdeen.

D. B. STEWART

CEREBELLAR SYNDROME FOLLOWING SODIUM AMYTAL

SIR.—I was much interested in Dr Bodman's observations last week on cerebellar effects following administration of 'Sodium amytal,' and would like to mention some observations of my own. These are recorded in my article on the anaesthesia of rabbits in the UFAW handbook on the *Care and Management of Laboratory Animals* (London 1947)—an article that was written in 1944-45.

Of rabbits anaesthetised with intravenous 'Nembutal' (sodium iso-amytal) or 'Evipan' (hexobarbitone), a fairly large proportion showed some degree of nystagmus, often quite slight, but sometimes very marked indeed, with synchronous nystagmoid movements of the whisker or even of the whole head. On at least one occasion

high my assailant could not face. Encouraged by this access I put up a barrage to cover my daughter's retreat to the other bank, and a somewhat more accurate barrage from two small boys, who welcomed the opportunity with glee, did the same for your somewhat battered correspondent, now incapable of vision from his right eye. For a week to come I received solicitous inquiries as to how I came by such a wonderful black eye. The um bruises being deeper were more slow in showing but impressive.

I still do not know whether a swan can break a man's arm with a blow of his wing, but I am entirely convinced that the bather should avoid the cock swan who is oppressed by family cares.

The peripatetic first-aid examiner (July 1) was unlucky in his viva candidates. I remember one particular session because five successive examinees answered my question on the treatment of gastric haemorrhage by rattling out parrot fashion "oyster soup." This was at Birmingham and as I was a Scot, I did not realise the intended answer was "ice to suck." I was pleased with this little misunderstanding just as I had been puzzled by the local delicacy which seemed to cause so many bell-ringers to be called "unfidum," translated as home fed ham.

Of course I related my examination experiences in the mess never thinking it would appear in *The Lancet* years later in an article on 'Hints to M.R.C.P. Candidates,' but the story had changed slightly in the interval. The scene was now an M.R.C.P. viva. The examiner asked my question, the poor candidates recommended the same soup. The examiner solved the conundrum by discovering that the candidates had all attended a cram class run by a Scotsman where there had been a bit of difficulty over his accent.

The *Times* fourth leader the other day discussed the birth of jokes and anecdotes, and wondered where they started. I know where this one started and I am still proud of my child, although it is a bit of a changeling.

As one of Mackintosh's diverted diploma graduates, at present peripatetically covering miles and miles in the relentless brilliance of Africa, may I send this titbit of tropical hygiene?

We met several tsetse control posts in Portuguese East Africa and some in Nvasaland and the procedure was roughly the same in each. We drove the car into a sort of garage shed, with doors at both ends and a thing that might have been a fume cupboard at the side. The doors were shut and an African solemnly spraved us here and there with a 'Flit' gun—we formed the impression that tsetse only fly in a band 3-4 ft from the ground. Then there was a pause for about 2 or 3 minutes, after which either the spraying was repeated or the door opened and we were freed. This interesting ritual took place several times we never knew whether we were entering or leaving the infested area. In Nvasaland the procedure was still further simplified. The African in charge informed us that as it was after 6 P.M. their post had stopped work and we could go straight through. Evidently tsetses keep trade-union hours.

After moving the patient into a better light I sat down to await what I expected would be a perfectly normal delivery. Nor did I have to wait long. Very soon the vertex peeped out shyly and was crowned, then the head was completely delivered and it was fully extended immediately afterwards. The thorax followed quickly, and the legs were born and waved feebly in the air. Next there was half an hour of apparent inertia without further progress. There seemed to be some difficulty in delivering the aftercoming abdomen, and I began to get worried. I had never seen or read of such a thing before and did not know what to do. There was no obvious distress, so I refrained from interfering (apart from testing an occasional reflex) and allowed nature to take its course. And rightly, for suddenly the abdomen slipped out easily, and the dragon-fly promptly reversed its position and began to dry its wings.

Pneumoconiosis in South Wales

Mr DAVID WILLIAMS asked the Minister of Fuel and Power how many miners in South Wales had continued their underground employment after being certified to be suffering from pneumoconiosis—Mr PHILIP NOEL BAKER replied On Dec 31 1949, 2372 men who had been given an assessment in respect of pneumoconiosis under the Industrial Injuries Act, 1948, were employed underground in the South Wales coalfield

Quarantine Medical Certificates

Major HOWARD JOHNSON asked the Minister of National Insurance whether she was aware that a certificate given by a general medical practitioner placing a person in quarantine could not be accepted for a benefit claim, and, in view of the fact that this cast a slur upon such a practitioner, whether she would amend the National Insurance (Unemployment and Sickness Benefit) Regulations in this respect—Dr EDITH SUMMERSKILL replied The medical officer of health is responsible for action to prevent the spread of infectious disease, and it is in accordance with the recommendation of the National Insurance Advisory Committee that he is also the authority for the issue of insurance certificates in these cases This implies no slur on general practitioners and I see no reason to alter the present provision

Medicine and the Law

The Wrong Bottle

At an inquest in Blyth last month the evidence showed that a woman, aged 23, had died through the inadvertent use of potassium citrate in an injection

A staff nurse with over twenty years' experience explained to the coroner that, when working at a clinic, she noticed that her flask of distilled water was almost empty She took it upstairs and asked an orderly to refill it, she held the flask while he filled it, she did not particularly notice the bottle which he used On the doctor's instructions she had to prepare two injections for a patient For the second injection she filled a syringe and handed it to the doctor, assisting him while he injected the contents into the patient's arm The patient, sitting in a chair, slumped forward and collapsed Attempts at artificial respiration failed and death followed

The jury returned a verdict of death from misadventure

The Duty to Inform the Coroner

At another inquest last month the resident surgical officer gave evidence that a woman was admitted to a Surrey hospital with general peritonitis An operation was conducted but nothing obvious was found to account for her condition, she died two days later At a limited necropsy an object was discovered which he at first thought was a piece of bamboo, it was suggested that it was the bone of a skate He signed a death certificate

The coroner commented that the death certificate was useless, no registrar would have accepted it, it meant that there was considerable delay before he himself was informed and considerable difficulty in carrying out a further necropsy The pathologist who gave evidence of this further examination said that he was unable to decide the cause of death because the body had been treated with embalming fluid, he thought the splinter looked like vegetable fibre of some sort The coroner stated that death obviously resulted from perforation of the bowel by an object 3 in long and pointed at both ends, "it may possibly be a fish bone, but I doubt it" He told the resident surgical officer that he should have informed the coroner's officer forthwith as soon as it was known that death was not due to natural causes "You seem," he said, "to have done a number of things which do not commend themselves to me" A verdict of accidental death was recorded

A Running Commentary by Peripatetic Correspondents

BLOODSHOT

Wintrobe O'Landsteiner Wiener FitzKahn
Lay in his lab on a satin divan

And sipping his saline he passed in review
The things he had almost decided to do,
Like writing his thesis on "Proof of a Theorem
Disproving that Serum is Plasma (or Serum)"
He thought of the days in the dawn of his youth
When, asking no more than Pursuit of the Truth,
With lenses all dirty and eyepieces scratched,
He counted corpuscles before they were hatched,
And many a time made a clear diagnosis
Of Multiple Red-cell Erythrocytosis
(He turned to a female technician and beat her
Until she remembered the height of the titre
He bade her get up and go dance a pavane
For Wintrobe O'Landsteiner Wiener FitzKahn)

Landsteiner Wintrobe O'Kahn de MacWiener
Arose and announced with unruffled demeanour,
"My private researches have recently shown
A way by which blood can be drawn from a stone
And pure inexhaustible rivers of gore
Extracted from crude sanguiferous ore"
"Thus tide of affairs we shall take at the flood
And pluck off the leeches who live on our blood—
Agglutinin courses the vessels of men
Remorselessly seeking agglutinin—
So Fate in fulfilment now fittingly sends
These bloodsucking bleeders to bloodthirsty ends!"
(The sauce for the gander is sauce for the goose,
The pips are as bitter as sweet is the juice—
"That donor will faint o'er he gets any greener!"
Said Landsteiner Wintrobe O'Kahn de MacWiener)

* * *

"A swan can break a man's arm with a blow of his wing" thus traditional childhood lore led me and my fellows in my very young days in the Thames Valley to regard these lordly birds with respect and even fear Increasing stature and experience of the vulnerability of the cock swan to a sharp poke in the neck with an oar or paddle led to modification of these feelings, and for years past I have looked on the swan merely as a pleasant adjunct to the landscape so long as he kept in his right place, and as an easily disposed of nuisance when he didn't But once again I have had occasion to modify my views

It was a lovely June day, my daughter and I were exploring, in a punt, a hitherto unvisited reach of river with a view to a bathe We found the reach ended in a steep weir, and it was easy to slide down its weed covered cement into the mild turbulence of the water at its foot Fifty yards away was the opposite bank towards which we swam and where we found a pair of swans with a brood of newly hatched cygnets receiving the attentions of a picnic party—a charming sight I left my daughter admiring it while I swam out into the pool A shout from the bank made me look round to find the cock bird bearing down upon me—neck feathers ruffled and wings half outspread so as to make him look twice his size, head proudly poised and with a malignant gleam in his beady eyes, viewed from the level of the water he presented a noble and formidable spectacle My immediate, and quite irrational, apprehension was of the beak in my eyes, and my reaction to shout "shoo" and splash at the downbearing menace The next moment the air above me was full of wings and I received a blow on the side of the head that knocked me silly When I was again in a position to observe events I found the malevolent fowl bearing down upon me from another angle To prevent my feet to the onslaught and to kick violently seemed sound tactics, but merely resulted in a further whirlwind of wings and a couple of blows on my right arm which numbed it from the shoulder down The next and subsequent attacks I evaded by diving and swimming under water towards the shallows, and thus somewhat ignominious procedure seemed to be the correct tactical answer Once in the shallows it was easy to heave a few stones in his direction—a threat

to a deep plane of anaesthesia of the shortest possible duration. We feel that this method is far easier than the more elaborate intubation methods described, and we are quite sure that many other units use this or a similar method.

Broadgreen Hospital, Liverpool

ACTH IN RHEUMATOID ARTHRITIS

SIR,—Dr Frank Marsh, in his letter last week commenting on our paper of June 24, suggests that intravenous adrenaline might be more effective than adrenaline given intramuscularly. We have treated six rheumatoid patients with intravenous adrenaline by continuous drip over 3-7 days. The physiological and therapeutic results have not differed substantially from those obtained by the intramuscular route. One of the difficulties connected with the intravenous method is the instability of adrenaline in weak solution, special precautions being required to prevent its rapid deterioration.

POSTURE

SIR,—In connection with my work on mental handicap, I have always been very interested in the relation between posture and body mechanics. When some years ago I became acquainted with the work of Matthias Alexander, to which Dr Barlow refers in your issue of July 1 I tried very hard to understand from his writing what he meant by "primary control." Then, during an interview, he showed me adjusting my head with his hands, the right position of the head in relation to the torso. I felt at once that in this position the muscles in the back of my neck, which previously had been strained, became completely relaxed, and head movement could be executed far more freely. Asked "why has man lost this 'primary control,' if he once possessed it?" Alexander replied "with the rapid advance of civilisation, instinctive control of the body has not kept pace with man's need," but he was unable to point out actual factors which had led to the loss of primary control.

This induced me to investigate the question on my own. By closely observing people, I found that whereas Europeans walked about with their heads slightly tilted backwards, Indians whose movements reflected far more ease and grace in walking and dancing, carried their heads in accordance with the "primary control." What was the reason? Then I remembered that peasant girls in southern countries, who carried heavy loads on their heads, balanced them freely, and had the same easy and graceful walk and the same beautiful movements. So I started to experiment by balancing things on my head, and after realising that they incessantly slipped down my back, I learned to adjust my head and became able not only to carry things whilst walking on a straight floor, but even to walk up and down stairs without dropping them. I constantly had to control my head position during the exercise, which I found was identical with the "primary control" position. The experiment showed the way to regain the lost control, without any elaborate teaching by devoting a few hours every day to the exercise of carrying things on one's head and trying all day long to keep the head in the same position.

But the question still remained "Why have we lost it? and why have these Indians and peasant girls not lost it?" The answer, it seems, is quite simple. Peasant girls in southern countries go barefooted during the greater part of the year, Indians do the same, and even if they do not go barefooted they walk in sandals without heels. In all the civilised societies of the West, children

wear shoes, even when learning to walk, and the toddler's shoe has a low heel. The heel is too low to disturb the general balance noticeably, but it nevertheless tilts the whole body very slightly forwards. If the child looks straight in front of him, his gaze lands at some distance on the floor instead of going parallel with it. To correct this visual handicap, a child whose vision is undisturbed will slightly retract his head to compensate for the forward tilt of the body, because the intervertebral joints move more easily at the neck than at any other part. Blind or very short sighted children will of course not adjust their sight and not retract the head. They are therefore constantly admonished to keep their heads erect (which actually means to tilt their heads back).

In my special field of mental deficiency I found that children suffering from visual disturbances and having lost their visual reflexes, do not lose their primary control, and seem always to droop their heads. If one gets a heelless shoe for these children, their posture is at once much improved, and their heads do not tilt forwards any more.

My experience tends to convince me that the head-neck torso relationship has a significant influence on body mechanics and that Alexander's "primary control" is of great importance in preserving ease and grace of movement. I have not formed any opinion as to its influence on disease. I have come to the conclusion, that the loss of "primary control" is due to the low heel of a toddler's shoe, and therefore originates early in childhood, if the "primary control" is not lost in childhood even a high heel cannot, it seems, destroy it. Finally I believe that in adolescence or adult life the acquisition of the right head position, and with it probably beauty and grace of movement, can be regained by learning to carry objects on one's head. With Alexander, I agree that we have lost a rather important instinctive control, but I disagree with him that such vague reasons as the "rapid advance of civilisation" account for this loss and contend that this is only due to one effect of civilisation—the slight slant of the body created by the heel of a baby's shoe.

LISE GELLNER

THE MEDICAL BILL

SIR,—Will you permit me, in what I conceive to be the interests of the whole body of medical students, to lay before your readers the manner in which this Bill, unless amended, will gravely injure those interests? The Bill begins this week its vital committee stage in the House of Commons so that if anything is to be done to help this relatively helpless but far from undeserving section of the community it is a case of now or never. There are always many thousands of them, and the harm to which I seek to draw public attention affects the future student hardly less than the present one. I write in the hope that this statement of simple fact will interest M.P.s (lay no less than medical) and doctors everywhere and that it may do something to convert the benevolent but still rather uncomprehending attitude of the British Medical Association into a vigorous and determined effort on their part to ensure justice at the hands of Parliament.

Here, then are the main points at issue. Each of them calls aloud for an amendment. Expressions of hope or sympathy, assurances, and advice to await regulations or orders are not enough. Nothing but actual enactment will avert the danger. Once it is plain that there is substance in a point why should not the Act incorporate it at once? Why leave it to a regulation or order?

1 The Bill seriously lengthens the period (already six years) of a student's training, and requires the extra time to be spent—after qualification but before registration—in compulsory resident, medical service in a

the rabbit assumed the typical cerebellar posture with the head drawn right over on to one shoulder. In these cases only a single dose of nembutal was given, though this might be repeated in the same rabbit a month later. In no case did we observe any lasting effects.

London W 1

J W SHACKLE

MULTIPLE-LEAD ELECTROCARDIOGRAMS

SIR,—I am obliged to Dr Josephs for his letter in your issue of June 17 regarding the significance of a broad S in lead I in the diagnosis of right bundle branch block. While it is true that in general right bundle branch block curves do show such a wave, the rule is not absolute. For example, in a case recently observed here the standard lead curves are those of "common-type" divergent bundle branch block with grossly broadened R and no S in lead I. In the chest leads of this patient, V1 shows M shaped initial deflections, with the intrinsic deflection falling 0.12 second after the beginning of R: there is thus right bundle branch block. In this case a diagnosis based on the standard leads only, and following the rule quoted by Dr Josephs, would have been erroneous.

There is no doubt that precordial leads are essential in the accurate diagnosis of bundle branch block curves.

Edinburgh

IAN G W HILL

TORSION OF THE GREAT OMENTUM

SIR,—Much as I enjoyed reading Mr Rejthar's article of May 27, I cannot agree that the condition is as rare as he suggests. Like some other writers on the subject, he mainly quotes articles from abroad while neglecting those at home. One of the first articles in this country was by Mr Reginald Vick¹, yet I cannot recall having seen this in any list of references. Another contribution rarely quoted is the one by Sir Cecil Wakeley². Nearly twenty years ago a paper by myself³ recorded seven cases, five of them from the London Hospital alone. I have no doubt that if the records of this and other great hospitals in London were further consulted, they would yield a goodly harvest of such cases.

Nor can I see why torsion of the *whole* of the structure should be insisted upon. If classification or specialisation in this particular instance is pushed to extremes, and we confine ourselves to pure intra abdominal torsion of the so-called *whole* of the great omentum, we shall succeed in getting a *rara avis* indeed. For instance, pure intra abdominal torsion automatically rules out torsion associated with any abdominal inflammatory lesion. The presence of an inguinal hernia renders the condition suspect, even if the appearances are that the hernia has nothing whatever to do with the condition—despite Lockwood's observation that in subjects under the age of 45 it is difficult to bring the omentum down to the level of the pubis.

I suggest that there is no such thing as torsion of the *whole* of the great omentum. As well might one expect the greater curvature of the stomach to tie itself in knots. What in actual fact happens in most cases is that there is a greater aggregation of tissue on the right side of the omentum, with pedicle formation *below* the level of the transverse colon, a condition which renders easy the twisting of the right half of the great omentum. Symptoms of torsion become acute when the vessels finally become occluded, and the condition is usually mistaken for acute appendicitis.

Like others, I have gone to some trouble to differentiate between acute appendicitis and torsion of the omentum³, yet twice since then I have diagnosed appendicitis to find instead at operation torsion of the omentum. On rare occasions the condition affects the left half of the

omentum, as in the case where two accessory spleens were found in the twisted mass, and then pain is felt on the left side.

In any event I fail to see why any portion, small or large, of the omentum should be excluded from any particular category of torsion. Distinguished surgeons in the past have been led to operate for symptoms arising from torsion of various sized portions of the omentum, but whether the portion be large or small, it is better to operate than allow the part to rot!

London, W 1

MICHAEL SMYTH

THREAT TO A SMALL GENERAL HOSPITAL

SIR,—St John's Hospital, Lewisham, which has been for nearly seventy years a complete general hospital, serving a population of a quarter of a million, is now threatened with dismemberment. This means that St. John's will lose inpatient facilities for six departments of medicine and surgery—gynaecology, dermatology, urology, orthopaedics, ENT, and psychiatry—and in addition children's beds are to be reduced by over half. Apart from the elimination thereby of its rôle as a general hospital, its efficiency and ultimate survival is menaced, and the community will be deprived of that free and alternative choice of opinion and treatment which it has hitherto enjoyed. This step is at variance with the promise of the Minister and his instructions to the regional board (RHB (49) 132¹).

This is no isolated threat, but one that confronts many hospitals of similar size throughout the country. Such hospitals as St John's have performed useful work to the community because of their completeness. Dismemberment can only be a retrograde step and should be energetically resisted. I urge these hospitals to take action before they are destroyed.

JOHN HOWKINS

GENERAL ANÆSTHESIA FOR BRONCHOGRAPHY IN CHILDREN

SIR,—The correspondence on this subject has aroused considerable interest here.

Nearly three years ago, Mr Philip Allison, of Leeds, demonstrated to one of us that when the swallowing reflex was abolished by anæsthesia, if iodised oil was placed in the pharynx it was sucked into the bronchial tree. Ever since then the method of bronchography used in this unit for children too young for the operation to be carried out under local anæsthesia, has been as follows.

The child is premedicated with atropine only. General anæsthesia is induced with open ether on a mask, possibly after preliminary induction with a very small dose of thiopentone, or ethyl chloride, or gas and oxygen, according to age. Anæsthesia is pushed to the point where cough and swallowing reflexes disappear. The mouth is then held open and 20 ml of iodised oil is poured in direct from the bottle. Sucking noises can be heard as the oil is drawn into the bronchial tree, and we allow the child to take six good breaths before films are exposed. No posturing at all is necessary, but better filling is obtained if, towards the end of the induction, carbon dioxide is added—preferably the patient's own. Films are taken in an anteroposterior and both oblique directions.

Immediately after the exposures, the child is turned upside down—our particular method is to place the child across the shoulder of the person carrying out the bronchogram—hanging from the hips with the head well down. Light percussion is carried out over the lung bases and a dish held to collect the iodised oil which trickles back. In fact, a very large part of the oil is so recovered, and the patient remains in this position until coughing commences.

We have now used this "drowning" method in approximately 250 cases without mishap, and in every case very good bronchograms have been obtained. The secret of success and safety is a very quick induction.

Assistant Thoracic Surgeon
T. CECIL GRAY
Senior Anaesthetist

Broadgreen Hospital, Liverpool

ACTH IN RHEUMATOID ARTHRITIS

SIR,—Dr Frank Marsh, in his letter last week commenting on our paper of June 24, suggests that intravenous adrenaline might be more effective than adrenaline given intramuscularly. We have treated six rheumatoid patients with intravenous adrenaline by continuous drip over 3–7 days. The physiological and therapeutic results have not differed substantially from those obtained by the intramuscular route. One of the difficulties connected with the intravenous method is the instability of adrenaline in weak solution; special precautions being required to prevent its rapid deterioration.

POSTURE

SIR,—In connection with my work on mental handicap, I have always been very interested in the relation between posture and body mechanics. When some years ago I became acquainted with the work of Matthias Alexander, to which Dr Barlow refers in your issue of July 1, I tried very hard to understand from his writing what he meant by "primary control." Then, during an interview, he showed me, adjusting my head with his hands, the right position of the head in relation to the torso. I felt at once that in this position the muscles in the back of my neck, which previously had been strained, became completely relaxed, and head movement could be executed far more freely. Asked 'why has man lost this "primary control," if he once possessed it?' Alexander replied "with the rapid advance of civilisation, instinctive control of the body has not kept pace with man's need," but he was unable to point out actual factors which had led to the loss of primary control.

This induced me to investigate the question on my own. By closely observing people, I found that whereas Europeans walked about with their heads slightly tilted backwards, Indians, whose movements reflected far more ease and grace in walking and dancing, carried their heads in accordance with the "primary control." What was the reason? Then I remembered that peasant girls in southern countries, who carried heavy loads on their heads, balanced them freely, and had the same easy and graceful walk and the same beautiful movements. So I started to experiment by balancing things on my head, and after realising that they incessantly slipped down my back, I learned to adjust my head and became able not only to carry things whilst walking on a straight floor, but even to walk up and down stairs without dropping them. I constantly had to control my head position during the exercise, which I found was identical with the "primary control" position. The experiment showed the way to regain the lost control, without any elaborate teaching, by devoting a few hours every day to the exercise of carrying things on one's head and trying all day long to keep the head in the same position.

But the question still remained: "Why have we lost it? and why have these Indians and peasant girls not lost it?" The answer, it seems, is quite simple. Peasant girls in southern countries go barefooted during the greater part of the year, Indians do the same, and even if they do not go barefooted they walk in sandals without heels. In all the civilised societies of the West, children

wear shoes, even when learning to walk, and the toddler's shoe has a low heel. The heel is too low to disturb the general balance noticeably, but it nevertheless tilts the whole body very slightly forwards. If the child looks straight in front of him, his gaze lands at some distance on the floor instead of going parallel with it. To correct this visual handicap, a child whose vision is undisturbed will slightly retract his head to compensate for the forward tilt of the body, because the intervertebral joints move more easily at the neck than at any other part. Blind or very short-sighted children will of course not adjust their sight and not retract the head. They are therefore constantly admonished to keep their heads erect (which actually means to tilt their heads back).

In my special field of mental deficiency I found that children suffering from visual disturbances and having lost their visual reflexes, do not lose their primary control and seem always to droop their heads. If one gets a heelless shoe for these children, their posture is at once much improved, and their heads do not tilt forwards any more.

My experience tends to convince me that the head-neck-torso relationship has a significant influence on body mechanics and that Alexander's "primary control" is of great importance in preserving ease and grace of movement. I have not formed any opinion as to its influence on disease. I have come to the conclusion that the loss of "primary control" is due to the low heel of a toddler's shoe, and therefore originates early in childhood, if the "primary control" is not lost in childhood even a high heel cannot, it seems, destroy it. Finally, I believe that in adolescence or adult life the acquisition of the right head position, and with it probably beauty and grace of movement, can be regained by learning to carry objects on one's head. With Alexander I agree that we have lost a rather important instinctive control, but I disagree with him that such vague reasons as the "rapid advance of civilisation" account for this loss and contend that this is only due to one effect of civilisation—the slight slant of the body created by the heel of a baby's shoe.

LISE GELLNER.

THE MEDICAL BILL

SIR,—Will you permit me, in what I conceive to be the interests of the whole body of medical students, to lay before your readers the manner in which this Bill, unless amended, will gravely injure those interests? The Bill begins this week its vital committee stage in the House of Commons, so that if anything is to be done to help this relatively helpless but far from underserving section of the community it is a case of now or never. There are always many thousands of them, and the harm to which I seek to draw public attention affects the future student hardly less than the present one. I write in the hope that this statement of simple fact will interest M.P.s (lay no less than medical) and convert the benevolent but still rather uncomprehending attitude of the British Medical Association into a vigorous and determined effort on their part to ensure justice at the hands of Parliament.

Here, then, are the main points at issue. Each of them calls aloud for an amendment. Expressions of hope or sympathy, assurances, and advice to await regulations or orders are not enough. Nothing but actual enactment will avert the danger. Once it is plain that there is substance in a point why should not the Act incorporate it at once? Why leave it to a regulation or order?

I. The Bill seriously lengthens the period (already six years) of a student's training and requires the extra time to be spent—after qualification but before registration—in compulsory, resident, medical service in a

the rabbit assumed the typical cerebellar posture with the head drawn right over on to one shoulder. In these cases only a single dose of nembutal was given, though this might be repeated in the same rabbit a month later. In no case did we observe any lasting effects.

London W 1

J W SHACKLE

MULTIPLE-LEAD ELECTROCARDIOGRAMS

SIR,—I am obliged to Dr Josephs for his letter in your issue of June 17 regarding the significance of a broad s in lead I in the diagnosis of right bundle branch block. While it is true that in general right bundle branch block curves do show such a wave, the rule is not absolute. For example, in a case recently observed here the standard lead curves are those of "common type" divergent bundle branch block with grossly broadened r and no s in lead I. In the chest leads of this patient, V1 shows M shaped initial deflections, with the intrinsic deflection falling 0.12 second after the beginning of r; there is thus right bundle branch block. In this case a diagnosis based on the standard leads only, and following the rule quoted by Dr Josephs, would have been erroneous.

There is no doubt that precordial leads are essential in the accurate diagnosis of bundle branch block curves.

IAN G W HILL

TORSION OF THE GREAT OMENTUM

SIR,—Much as I enjoyed reading Mr Rejthar's article of May 27, I cannot agree that the condition is as rare as he suggests. Like some other writers on the subject, he mainly quotes articles from abroad while neglecting those at home. One of the first articles in this country was by Mr Reginald Vick¹, yet I cannot recall having seen this in any list of references. Another contribution rarely quoted is the one by Sir Cecil Wakeley². Nearly twenty years ago a paper by myself³ recorded seven cases, five of them from the London Hospital alone. I have no doubt that if the records of this and other great hospitals in London were further consulted, they would yield a goodly harvest of such cases.

Nor can I see why torsion of the *whole* of the structure should be insisted upon. If classification or specialisation in this particular instance is pushed to extremes, and we confine ourselves to pure intra abdominal torsion of the so-called *whole* of the great omentum, we shall succeed in getting a *rara avis* indeed. For instance, pure intra abdominal torsion automatically rules out torsion associated with any abdominal inflammatory lesion. The presence of an inguinal hernia renders the condition suspect, even if the appearances are that the hernia has nothing whatever to do with the condition—despite Lockwood's observation that in subjects under the age of 45 it is difficult to bring the omentum down to the level of the pubis.

I suggest that there is no such thing as torsion of the *whole* of the great omentum. As well might one expect the greater curvature of the stomach to tie itself in knots. What in actual fact happens in most cases is that there is a greater aggregation of tissue on the right side of the omentum, with pedicle formation *below* the level of the transverse colon, a condition which renders easy the twisting of the right half of the great omentum. Symptoms of torsion become acute when the vessels finally become occluded, and the condition is usually mistaken for acute appendicitis.

Like others, I have gone to some trouble to differentiate between acute appendicitis and torsion of the omentum³, yet twice since then I have diagnosed appendicitis to find instead at operation torsion of the omentum. On rare occasions the condition affects the left half of the

omentum, as in the case where two accessory spleens were found in the twisted mass, and then pain is felt on the left side.

In any event I fail to see why any portion, small or large, of the omentum should be excluded from any particular category of torsion. Distinguished surgeons in the past have been led to operate for symptoms arising from torsion of various sized portions of the omentum, but whether the portion be large or small, it is better to operate than allow the part to rot!

London W 1

MICHAEL SMITH

THREAT TO A SMALL GENERAL HOSPITAL

SIR,—St John's Hospital, Lewisham, which has been for nearly seventy years a complete general hospital, serving a population of a quarter of a million, is now threatened with dismemberment. This means that St John's will lose inpatient facilities for six departments of medicine and surgery—gynaecology, dermatology, urology, orthopaedics, ENT, and psychiatry—and in addition children's beds are to be reduced by over half. Apart from the elimination thereby of its role as a general hospital, its efficiency and ultimate survival is menaced, and the community will be deprived of that free and alternative choice of opinion and treatment which it has hitherto enjoyed. This step is at variance with the promise of the Minister and his instructions to the regional board (RHB (49) 132¹).

This is no isolated threat, but one that confronts many hospitals of similar size throughout the country. Such hospitals as St John's have performed useful work to the community because of their completeness. Dismemberment can only be a retrograde step and should be energetically resisted. I urge these hospitals to take action before they are destroyed.

hospital or institution. In decreeing this new burden the Bill makes no distinction between future students and present students. Hundreds, perhaps thousands, of the latter signed on and have since done years of this training, on the old conditions. How can the new burden be justly thrust upon any of these against his will?

2 There is no upper limit to this extra period of compulsory resident service. Subject to the approval of the Privy Council the General Medical Council is empowered to extend it indefinitely (Sec 2 [1]).

3 A student is to be entitled to registration only if the diploma granting "body are satisfied that his service has been satisfactory" (Sec 2 [2]), but though dissatisfaction may thus prejudice or even end his medical career, the Bill gives him neither a right of appeal nor even a right to a statement of the grounds of the alleged dissatisfaction.

4 But for this Bill the qualified student would himself be the junior house officer (who is of course at present a full blown doctor), while under it he will be doing, in effect, the junior house officer's work without either the doctor's status or any right even to the house officer's remuneration. I quote Mr Aneurin Bevan (*Hansard*, 27th June, 1950, col 2135).

'For the most part it is anticipated that he will hold what are in effect junior house appointments, that is, posts as house surgeon or house physician. At present these are held by doctors after registration.'

Trifles such as remuneration, status (even within the hospital and under supervision, like the present junior house officer, by the senior staff), rights, privileges, and powers are amply ignored, and, so far as any express provisions go, the Bill contents itself with (Sec 4 [3]) decreeing degradation. I also wonder what those words "for the most part" mean?

5 The Bill requires the "intern" (hitherto junior house officer) to serve in two successive appointments, one medical, the other surgical, but contains no provision against the possibility that he may be quite unable at the proper time to obtain one, or both, of them. There is in it nothing postdating its operation till it is certain that there not only are, but will continue to be, enough "approved" appointments to absorb, without delay, the whole of each successive "entry." And the unfortunate who notwithstanding due diligence may hereafter fail, either because there is no vacancy for him at the right moment or for any other reason (such as dissatisfaction, well or ill founded), to secure without delay, or at all, either or both of the indispensable jobs will have plenty of leisure for repenting his un wisdom in having trusted at this stage to hopes and assurances, rather than to the curt finality of an amendment.

6 The Bill contains no provision for the families of the married men, now—for the first time in the history of medical training—to be compulsorily separated from them for this additional period, which under the Bill is exceedingly unlikely to be less than twelve months, but may well (once the thin end of the wedge has been successfully introduced) be greatly more.

Guildford, Surrey

W B MANLEY

SIR,—The Medical Bill, 1950, is now, after quite extra ordinarily rapid progress through the House of Lords and through its second reading in the House of Commons, very shortly to reach the statute book.

The British Medical Students' Association has given very careful thought to those parts of the Bill which deal with alterations in medical training. Many important provisions of the Bill are not accurately defined and a very great deal will depend upon the way in which they are finally interpreted by the General Medical Council. For this reason I should like to draw attention to one significant point which is giving rise to considerable

anxiety among medical students—namely, that the newly qualified and "provisionally registered" doctor will be allowed to practise only in an approved hospital and under supervision. At the moment there are a large number of well qualified and keen young doctors whose financial circumstances will not permit them to serve for two six monthly house appointments even though they might supplement their earnings by locum tenens positions between such appointments. If and when the Bill is enacted, a provisionally registered doctor will no longer be allowed to act as locum tenens, and unless some central fund is provided there are likely to be many young doctors who will suffer financial hardship in the period between qualifying and obtaining their first appointment and also in the interim period between the two compulsory hospital appointments.

P L C DIGGORY

DUAL CAUSE OF RAPID DEATH

SIR,—The following post mortem findings must be unusual.

A boarding house keeper, aged 53, was last seen alive by her husband when he left for work at 7.45 A.M. On his return at midday, he found her lying between two beds, which she had obviously been making. Apart from a local mastectomy fifteen years previously, she had not had a day's illness or complaint. Her death was reported to the coroner. At necropsy there was a large recent left-sided cerebral haemorrhage. There was also a haemopericardium, due to spontaneous rupture of the aorta just above the aortic valve. This rupture probably occurred shortly after the onset of the cerebral haemorrhage.

Either event would, of course, have caused death.

INJURY FROM ELECTRIC WASHING MACHINES

SIR,—I read with great interest Mr Wade's letter last week. He says that domestic washing machines fitted with electrically driven wringer rollers are rare in the British Isles. In fact, however, of the six best known makes of electric machine, four have power driven rollers, one has a crank operated wringer, and one uses a centrifuge method of moisture removal. As regards Mr Wade's comment on the need for a safety device on power roller machines, all four of the machines mentioned above have a clutch lever on the frame to disengage the drive and a horizontal bar near the rollers to separate them by spring action at the slightest pressure.

Lidget Green Bradford

T J WINX

EXPENSIVE PRESCRIPTIONS

SIR,—In your leading article last week you wrote "But anyone who is anxious to see the limited funds of the N.H.S. used on essentials must be distressed by merely casual expenditure on remedies which are obtainable more cheaply under another name." You also wrote "'new drugs of proved value not yet standard' should be freely prescribable without reservation."

There is one source of waste which could be removed by the stroke of a pen. I refer to purchase tax of 33½% payable on new drugs until they have been specifically exempted. I have in mind thiosemicarbazone, on which you reported on Feb 11 (p 264) and the efficacy of which, in suitable cases, was endorsed at the recent meeting of the British Tuberculosis Association at Oxford. There can be little doubt that such a drug should be prescribed, if only for a limited trial at present, but that the Exchequer should mulct the National Health Service of an extra 6s 8d for every pound spent on chemical trial seems to me quite absurd.

RESEARCH UNIT, MEDICAL
RESEARCH COUNCIL

The difficulty of finding enough nurses and hospital beds for patients suffering from pulmonary tuberculosis is one of the most serious medical problems of today. Early diagnosis means little if it is followed by nine months' wait for treatment, and, as the Minister of Health stated recently, there are at present 11,000 patients in England and Wales awaiting admission to sanatoria. Much of the problem would be solved if general hospitals would allocate beds for this purpose. Yet some fear that such a policy would result in a greater tuberculosis morbidity in the nurses of these hospitals since we have found that patients with pulmonary tuberculosis can be nursed in the separate tuberculosis wards of a general hospital with little risk to nurses, provided certain precautions are adopted, we are recording our findings. The Mantoux conversion rate and the tuberculosis morbidity have been studied for the student nurses entering the hospital between 1945 and 1949, and the results are compared with those obtained by the Prophit Tuberculosis Survey (1948).

THE HOSPITAL

Central Middlesex is a large regional hospital admitting every type of case. During the war the tuberculosis wards had been evacuated and as a result complete segregation of the tuberculous patients was not possible. Many nurses, including a few who were tuberculin-negative, had been to a nearby sanatorium for tuberculosis training. By September, 1945, two wards with 58 tuberculosis beds had been reopened and the policy of prevention of infection of nurses described below has been enforced since that time.

THE NURSES

Between July 1945, and May, 1949, 312 student nurses entered the hospital. Of these, 252 entered through the preliminary training school (P.T.S.) and therefore could not reach the wards until October, 1945—i.e., after the reopening of the tuberculosis wards and the institution of the policy of control of infection. The remaining 60 nurses, already partially trained, entered the wards direct between October, 1945, and May, 1949. Since 57 nurses left from the P.T.S., only 255 out of the 312 nurses actually entered the wards, and it is on these 255 that the initial tuberculin testing figures are based—although, as explained below, only 190 of them were tested. Moreover, since 22 nurses were still in the P.T.S. at the end of May, 1949, only 233 nurses had worked in the wards up to this date. Details of the nursing population are as follows:

Entered between July 1945 and May 1949	252	312
Entered through P.T.S.	60	
Entered general wards direct		
Nurses leaving from the P.T.S.	57	
	255	
Nurses reaching wards		
Entered wards before May 1949	233	
Still in P.T.S. May 1949	22	
Tuberculin tested	190	
Not tested	65	

Of the 65 not tested 31 left within three months of entering the wards and 8 within six months the remaining 26 came from sanatoria where they had been tested already. Of the 190 nurses receiving their initial tuberculin test, 71% were aged twenty-one or under at the time. Their age distribution when tested was as follows:

No. of nurses	Age (yr.)	No. of nurses	Age (yr.)
38	17	9	24
40	18	8	25
25	19	5	26
20	20	1	27
12	21	6	28
10	22	2	29
4	23	10	30 and over

Details of the country of origin of all the nurses were not kept but a survey in 1944 had shown that 70% were English and 14% were Welsh or Irish, and there is no reason to believe that the present group was very different.

CONTROL OF INFECTION

Various precautions are adopted in this hospital to diminish the risk of tuberculous infection and to assist early diagnosis should disease develop.

Tuberculin Testing—During the period surveyed the nurses were tested soon after they entered the general wards (although they are now tested in the training school). Non reactors are retested at three-monthly intervals until conversion. After conversion the nurse is interviewed and told to report if at any time she is not feeling well. A sedimentation rate is done and an X-ray film taken every 3 months for a year. She is not allowed to work on a tuberculosis ward for one year after conversion.

Chest X rays—All nurses have a chest film taken before entry and then at regular intervals.

The Undiagnosed Case of tuberculosis on the general ward is one of the chief sources of infection. Ideally a chest film should be taken on every patient admitted to hospital but this is not possible at present. However, X-ray films are taken of nearly all chest cases admitted, thus keeping the number of unsuspected cases of pulmonary tuberculosis down to a minimum.

Immediate Transfer—When a diagnosis of open tuberculosis is made on a patient in a general ward, he is immediately transferred to one of the tuberculosis wards. Since one emergency bed on each of these wards is kept vacant for the purpose, transfer within forty-eight hours is nearly always possible.

The Tuberculosis Wards—Tuberculin negative nurses are not allowed to work on these wards. The floors are oiled, the nurses wear gowns while at work and in addition wear face masks while bed making. No nurse handles the sputum mugs, in view of the known susceptibility of young nurses to infection, this work is done by an elderly male porter. With all patients, particular stress is laid on the need to stop coughing.

TUBERCULIN TEST

The tuberculin used is the protein purified derivative (P.P.D.). The first dose, 0.1 ml. of P.P.D. (equivalent to 0.0002 mg. P.P.D. per ml. or 1/10,000 Old Tuberculin), is injected intradermally. If there is no reaction after forty-eight hours, a repeat with P.P.D., last dose ($\equiv 0.1/100$) is given. Those who react doubtfully after the first injection are given P.P.D., intermediate dose ($\equiv 0.1/1000$). The standard adopted is that used by the Prophit survey—i.e., a positive reaction is one with 5 mm. or more of infiltration.

University of Sheffield

Mr C Scott Russell has been appointed to the new full time chair of obstetrics and gynaecology.

Mr Russell qualified M.B. at Edinburgh in 1935 and after holding various hospital appointments was successively research assistant and first assistant in the Nuffield department of obstetrics and gynaecology at Oxford. In 1940 he went to Manchester as assistant director in the university department of obstetrics and gynaecology and resident obstetrician and gynaecologist at St Mary's Hospitals and last year he was appointed to his present post of reader. He became F.R.C.S.E. in 1939 and M.R.C.O.G. in 1940. Mr Russell is the author of two books—*Child-bearing Years* and *Obstetrics and Gynaecology*—both published in 1947.

Dr William Whitaker has been appointed lecturer in medicine and Dr R F Crampton assistant lecturer in physiology. The following part time appointments have been made. Dr C S Darke, lecturer and clinical teacher in chest diseases, and Dr D J Campbell, lecturer and clinical teacher in venereal diseases.

Royal College of Surgeons of England

Election to the Council—Mr Hedley Whyte, Mr E W Riches, and Sir Arthur Porritt have been elected members of the council. The result of the poll was as follows:

	Votes
A HEDLEY WHYTE (Royal Victoria Infirmary Newcastle upon Tyne)	904
E W RICHES (Middlesex Hospital)	831
SIR ARTHUR PORRITT (St Mary's Hospital)	691
IAN AIRD (Postgraduate Medical School of London)	679
R L NEWELL (Royal Infirmary Manchester)	661
V W DIX (London Hospital)	398
N L ECKHOFF (Guy's Hospital)	296

Royal College of Surgeons of Edinburgh

Honorary fellowship of the college has been conferred by Mr W Quarry Wood, the president, on Dr D C Balfour, director of the Mayo Foundation and past president of the American College of Surgeons, and on Dr A W Allen, a former president and now chairman of the board of regents of the American College of Surgeons.

Royal College of Surgeons in Ireland

The following have been admitted to fellowship of the college:

Dr H T P Young has been appointed inspector of retreats under the Inebriates Acts, 1879-98.

Homœopathic Congress

A joint congress of the Council of the International Homœopathic League, the Faculty of Homœopathy, and the British Homœopathic Congress is to be held at the Royal London Homœopathic Hospital on July 20-28.

Lists of Principals with Assistants

The General Medical and Pharmaceutical Services Regulations and the model allocation scheme allow a general practitioner who employs a permanent assistant (apart from a trainee assistant) to increase his list of patients by 2400 beyond the ordinary maximum. In a letter to executive councils, the Ministry of Health states that "in general it would be reasonable to regard as a permanent assistant not only a full time assistant but also an assistant regularly employed part time for at least one half of the time that a full time assistant would normally serve the practice, that in the case of such a part time assistant it would be reasonable for an Executive Council to agree that the principal's list might be increased by a proportion of 2400 approximately equal to the proportion of the time given by the assistant, but that where the assistant is employed for less than half time no increase in his principal's list should be permitted." These criteria should it is suggested, be applied only to future cases in which the employment of an assistant is approved, there should be no change in arrangements

W H O Regional Office for Western Pacific

Dr I C Fang is temporarily to direct W H O activities in the Western Pacific, for which a regional organisation is to be set up next year. The temporary office is to be in Hong Kong.

A C T H in the U S A

Adrenocorticotrophic hormone (A C T H) has now been made available to all 6572 hospitals in the U S A that are registered by the American Medical Association, according to a B.U.P. report.

CORRIGENDUM *Convalescence for Diabetics*—In our note on two convalescent homes for diabetics (July 1, p. 35) we described the home at Burley on the Hill, in Rutlandshire, as sponsored by the British Red Cross Society. The home, though originally founded by the Red Cross, now comes under the Leicester No 2 Hospital Management Committee of the Sheffield Regional Hospital Board, and has been renamed the Burley on the Hill Auxiliary Hospital.

YOUNG—On June 28 in Chichester John Charles Young M.R.C.S. aged 78

primary infection X ray films of the remaining are all normal

Case 1—Aged 18, English She was tuberculin negative May, 1947, to January, 1948 In May, 1948, she developed erythema nodosum and was found to be tuberculin positive Her erythrocyte sedimentation rate (E.S.R.) was 38 mm X ray film showed a primary focus in the right mid zone enlarged hilar glands She went to a convalescent home and was away from work for six months

Case 2—Aged 19 Entered in March, 1947 She was tuberculin negative from July, 1947, to January, 1948 In May, 1948, she developed a mild attack of erythema nodosum X ray film of the chest was normal In May, 1948, she was tuberculin positive She was away from work for a month, though cases of erythema nodosum usually have a short convalescence

Among the 12 nurses undergoing conversion before tuberculosis wards were opened, 4 (33%) were ill on account of primary infection and were off sick for a total of twenty nine months, 2 had erythema nodosum, 1 had enlarged hilar glands, one had malaise and night sweats with a raised E.S.R., and one had a fever for three weeks associated with a primary focus in the right lung

MORBIDITY

The criteria for morbidity adopted are those of the Prophit survey, which are

Clinically active pulmonary tuberculosis
Latent subclinical pulmonary tuberculosis, progressive
Latent subclinical pulmonary tuberculosis non progressive
Non pulmonary tuberculosis
Pleural effusion.

Cases of erythema nodosum unaccompanied by any other tuberculous manifestation are not included (Case 2 was the only one)

The morbidity figures are based on cases admitted to the staff sick bay Nurses with symptoms of tuberculous disease, those with progressive radiological lesions, and those with lesions of doubtful activity are admitted for assessment Since X ray films taken before 1945 are no longer available, cases of latent subclinical pulmonary tuberculosis, non progressive, have been excluded from the morbidity figures, but allowance is made for this in comparing them with the results of the Prophit survey In all, 312 nurses spent a total of 346 years in the hospital up to May, 1949, including time spent in the wards For the reasons already given above 233 nurses actually worked on the wards during the period, for a total of 290 years Three nurses whose X-ray films were normal on admission developed tuberculosis, one of these has been described (case 1) The other two (cases 3 and 4) developed pleural effusion while in the training-school. Since pleural effusion usually occurs six to twelve months after Mantoux-conversion (Thompson 1949b) it is probable that infection occurred before entry

Case 3—Aged 26 Her sister had pulmonary tuberculosis treated P.T.S. on Oct 28, 1946 A few days later she developed left pleural pain and on Nov 19 reported sick with a left pleural effusion Guineapig test on pleural fluid was positive She returned to duty on Aug 27, 1947, after seven months' illness

Case 4—Aged 18 Entered P.T.S. on Sept 1, 1947 On Nov 4, she was admitted to the wards with a right pleural effusion Culture of fluid for tubercle bacilli was negative but she made a satisfactory recovery but did not return to nursing

Two other nurses were not free from disease on entry

Case 5—Aged 27 English She had had tuberculous cervical glands as a child, and Bazin's disease for some years On entry in January, 1948 radiography showed enlarged foci in the left upper zone and in the neck. She was tuberculin positive In January, 1948 she developed enlarged right axillary lymph glands These were excised in September of that year and showed tuberculous adenitis She was away from work for seven weeks

TABLE II—COMPARISON OF MORBIDITY AT CENTRAL MIDDLESEX HOSPITAL WITH THAT OF THE PROPHIT SURVEY

Group of nurses	Observation years	Cases of tuberculosis	Annual rate/1000
Prophit			
Group A nurses	2819.5	52	18.4
Group B nurses	5771.25	50	8.7
Groups A and B together	8590.75	102	11.9
All C.M.H. nurses (312)	346.0	3	8.7
C.M.H. nurses in wards (233)	290.25	1	3.4

Note—The Prophit survey rates have been calculated after deducting cases of latent subclinical pulmonary tuberculosis non progressive for the reason given in the text

Case 6—Aged 22, Irish Entered in April, 1948, when her X ray film showed a small left apical lesion, later shown to be non progressive She was tuberculin positive In November, 1948, she developed right pleural pain Radiography showed consolidation and later collapse of the right middle lobe E.S.R. 44 Bronchoscopy showed no bronchial obstruction and the condition slowly resolved Though it may have been tuberculous, sputum and bronchial and laryngeal swabs were all negative for tubercle bacilli. She returned to duty after six months and is now well

Thus out of a total of 312 nurses, 3 developed tuberculous disease as defined by the Prophit survey, for which they were off sick for nineteen months altogether (cases 1, 3, and 4) Two returned to full duty and the third, although she left, was considered medically fit to return In 2 of these 3 cases it is probable that infection occurred before they started training (cases 3 and 4) The other nurse (case 1) had symptoms as a result of her primary infection

Apart from the above, one nurse had a relapse of tuberculous adenitis (case 5), one developed a collapsed middle lobe of doubtful etiology (case 6), and one had a mild attack of erythema nodosum (case 2) The last 3 were off sick for a total of eight months

Morbidity rates cannot be considered significant when the numbers are so small However table II shows those of the Central Middlesex nurses and the Prophit survey

Although the use of B.C.G. is probably most valuable for increasing the nurse's resistance to infection, there is a danger it may be adopted without the precautions that have been described We have shown that these precautions by themselves can considerably reduce tuberculous infection

USE OF BEDS FOR TREATMENT

Apart from its function in the prevention of infection, the tuberculosis unit in the Central Middlesex Hospital has been invaluable in other directions Most deaths from phthisis occur in the 15-50 year age groups, in which the disease is often acute, with rapid spread. Such cases must be regarded as medical emergencies Diagnosis should be established at the earliest

Fig 2—Case 7 on Dec. 17 1949

moment and must be followed by immediate treatment It is a grave reflection on national administration that, throughout Britain, thousands of phthisical patients are

Of the 255 nurses who entered the general wards 190 were tested. The result of the initial test was

	Tuberculin positive		Tuberculin negative	
	No	%	No	%
Nurses tested (190)	141	74	49	26
Previously trained (25)	24	96	1	4
With no previous training (165)	117	71	48	29

COMPARISON WITH PROPHIT SURVEY

The Prophit survey compared the Mantoux conversion rate and the tuberculosis morbidity of nurses from two groups of hospitals. Group A hospitals admitted all classes of patients including cases of advanced tuberculosis and most of them had tuberculosis wards. Group B hospitals did not admit such "heavy" cases, and only one of them had a tuberculosis ward for a part of the survey. Central Middlesex Hospital corresponds to a group A hospital in the type of case which is admitted, and in having tuberculosis wards.

A considerable part of the Prophit survey was carried out during the war, whereas all the present survey period was post war, and this fact would operate in favour of the present series. Poorer ward ventilation during the war probably increased the risk of infection and therefore of Mantoux conversion. In addition poorer food and other stresses of war may have decreased the nurses' resistance and helped to increase the morbidity.

MANTOUX CONVERSION RATE

The Mantoux conversion rate was calculated for (i) all non reactors (45), who entered the wards between Oct 1, 1945 and May 31, 1949, together with (ii) those non reactors (10) who were already in the wards on Oct 1, 1945.

(i) Non reactors on entry (out of 190 tested)	49
Not re tested	4
Re tested	45
(ii) Non reactors already in wards, October 1945	10
Total for calculation of Mantoux conversion rate	55

Non reactors who had not left the hospital were re tested up to May, 1950. Altogether 55 nurses were tested more than once, and of these 19 converted. They were, for the most part, re tested every three months, though owing to practical difficulties there were a number of

Fig 1—Percentage of persons initially tuberculin-negative who became positive in the first three years. Comparison of results at the Central Middlesex Hospital with those in the Prophit survey.

Table 1 shows the conversion rate compared with that of various groups in the same survey. At the end of a year the conversion rate for Prophit group A nurses

* The statistical test used in comparisons in this paper was the usual one for the difference of two percentages with the number of nurses tested in each group as the denominator. Where there was any doubt and in the main comparison with Prophit group B nurses the χ^2 test was used as a check.

was 79.6%, for Prophit group B nurses 54.1%, Central Middlesex nurses 27.9%. At the end of two years the rates were 92.7%, 78.8%, and 44.8%, differences between the Central Middlesex Hospital and group B rate at one year and at two years are statistically significant at the 0.1% level. A for Central Middlesex Hospital rates differ from the group A rates. The differences between Central Middlesex Hospital rate and the rates for medical students and female controls are not

As mentioned above, tuberculin testing started in January, 1944, some twenty months before the isolation wards were opened. During this early period non reactors were re tested, of whom 12 were. The conversion rate at the end of the first year

TABLE 1—COMPARISON OF CONVERSION RATE IN NURSES CENTRAL MIDDLESEX HOSPITAL WITH CONVERSION RATE FOUND BY THE PROPHIT SURVEY

% of Mantoux negative entrants positive at 3 monthly intervals after first test						C.M.H. nurses convert ing in 3 months since last test	C.M.H. nurses Nurs test

30			48.9			0	1
33			48.9			0	3
36	95.1	92.7		75.5	57.1		

these nurses was 57.8%. The difference between this rate and that for the first year in the second period (27.9%) is significant at the 5% level but not at the 1% level. Clearly not much weight must be attached to this result, where only 21 nurses are concerned. It is mentioned here for completeness and to show that the rate for this period is at least not smaller than that for the second period.

It was possible that the nurses in group (ii) might include some who were highly resistant to conversion and that the combined rate for groups (i) and (ii), given in table 1, might be artificially low for this reason. This was not so is demonstrated by the fact that rates for group (i) alone were 24.4% in the first year and 43.1% in the second year—both smaller than the corresponding rates for groups (i) and (ii) combined.

Since it is agreed that the Mantoux conversion rate of a group of persons is the best index of the degree of their exposure to tuberculous infection, these results strongly suggest that the precautions described have been effective in reducing the risk of infection among nurses. Other relatively low rates among nurses have been reported. Court (1949) found a conversion rate of 36% in the first year in a similar type of hospital. From New Zealand, North (1941) reported a rate of 34.6% and Thompson (1949a) a rate of 14.9% in the first year among hospital nurses. It is interesting to note that all the above hospitals used similar precautions to those recommended by the Prophit survey which are essentially the same as those used at this hospital.

MANIFESTATIONS OF MANTOUX CONVERSION

As has already been stated above, of the 55 non reactors re tested after October, 1945, 19 underwent Mantoux conversion. Of these, 2 (10.5%) were admitted to sick bay on account of symptoms due

been divorced from medicine for too long, and thousands of students have qualified and entered practice with little or no knowledge of the early manifestations of this disease. Yet in England and Wales this disease is responsible for 400 deaths a week. Tuberculosis wards in general hospitals can but lead to a revival of interest in this common disease. Opportunities for undergraduate and postgraduate instruction can be increased and should lead to better standards of diagnosis and treatment throughout the country. Tuberculosis must be brought back into the main stream of medicine.

SUMMARY AND CONCLUSIONS

Studies of Mantoux conversions show that the risk of infection to nurses in a general hospital need be little greater than that to a comparable section of the general population.

At the Central Middlesex Hospital, the Mantoux conversion rate of 27.9% for the first year is significantly lower than rates found for student nurses by the Prophylactic Survey (which reported 79.6% for group B hospitals, and 54.1% for group A hospitals). This low rate is attributed to precautions used at this hospital. There is a risk that the introduction of BCG vaccination may lead to the continued neglect of these other preventive measures which we have found to be effective.

No sputum positive case should be allowed to stay in a general ward for more than twenty-four hours after diagnosis. The presence of infectious cases in general wards could be avoided by mass radiographic examination of all admissions and of outpatients.

Much active treatment of the tuberculous can be efficiently given at home, if appropriate facilities are available to the chest physician in the local general hospital.

Tuberculosis should be treated scientifically and expeditiously in every major hospital or group of smaller hospitals.

All nurses and medical students should study this disease intensively.

We are grateful to Dr. Marc Daniels and to Dr. J. N. Morris for helpful criticism and advice, and to Dr. J. Sakula, who carried out the earlier tuberculin testing.

 VISITING PHYSICIAN

E C MCCLURE
 M.B. Belf.
 LATE HOUSE PHYSICIAN

CITY GENERAL HOSPITAL, STOKE-ON-TRENT

THE remarkable action of 'Cortisone' and adrenocorticotrophic hormone (A.C.T.H.) on rheumatoid arthritis (Hench et al. 1948) raises the question whether other, more readily available, compounds exist with comparable therapeutic properties. This problem is of more than theoretical interest, for supplies of cortisone and A.C.T.H. are unlikely to increase greatly in the near future and it may be many years before supplies can meet the very large potential demand. Moreover, even if supplies were abundant side effects might seriously limit the usefulness of these two substances. In the search for substances with similar properties, much attention has naturally been given to steroid compounds (Lewin and Wassén 1949, Alexander and Duthe 1950, Kersley et al. 1950).

The clinical investigation described here began with a trial of a series of steroids in cases of active rheumatoid arthritis. The compounds tested included the following: desoxycholeic acid, Δ_1 pregnenol 17 β one 3, Δ_1 pregnenol 17 α one 3, and Δ_1 pregnenol 3 β one 20 (Δ_1 pregnenolone). With the exception of desoxycholeic acid, which was given intravenously, each of these compounds was given intramuscularly, usually as the acetate dissolved in a mixture of glyceride ester oils in a daily dosage of 200 mg. for at least 3 weeks. Owing to restricted supplies, it was possible to treat only two, or at the most three, cases with each of these compounds. No objective improvement was noted following the administration of desoxycholeic acid (2 cases), Δ_1 pregnenol 17 β one 3 (3 cases), or Δ_1 pregnenol 17 α one 3 (3 cases).

Δ_1 pregnenolone was the next compound to be investigated. In the hands of Freeman et al. (1950) this substance has benefited cases of rheumatoid arthritis, and Davison and Koets (1949) have described favourable results from its use in ankylosing spondylitis.

CLINICAL MATERIAL AND METHODS

In a preliminary trial, two women with rheumatoid arthritis and one man with ankylosing spondylitis were treated with Δ_1 pregnenolone. The case of ankylosing spondylitis and one of the cases of rheumatoid arthritis showed early objective improvement, and it was therefore decided to give this substance a more extended trial. As supplies of pregnenolone were limited, it was possible to treat only seven further patients, and this further investigation was confined to cases of rheumatoid arthritis. The whole group consists, therefore, of one case of ankylosing spondylitis and nine cases of rheumatoid arthritis.

The criteria for the selection of cases were that the patients should be suffering from well established rheumatoid arthritis of at least 1 year's duration, and that the disease should be active as evidenced by pain, soft-tissue swelling, and a blood sedimentation rate (B.S.R.) consistently raised above 25 mm. in 1 hour (Westergren). In the accompanying table, the ten cases in the series have been graded according to the stage of the disease, by the standards which Steinbrocker et al. (1949) recommended. Except for the patient with ankylosing spondylitis, all remained in hospital under close supervision throughout the trial, and the seven cases in the more extended trial were observed in hospital for 1 month before treatment was begun. Initial laboratory investigations included full blood count, blood uric acid, blood urea, and blood protein estimations, and X-ray examination of all affected joints. The B.S.R. was measured once, and often twice, each week throughout the period of observation and trial.

A goniometer was used for measuring the range of joint movement in the shoulder, elbow, wrist, and knee. As a method of precision, goniometry of joint movements is open to criticism, but we felt that it was extremely important to employ some recordable form of objective measurement. In practice, moreover, we were surprised at the constancy of the readings obtained by each of us independently from week to week in the same cases. All measurements were recorded to the nearest 5°, and a change of +10° or -10° was taken to be significant. Movement at the shoulder was recorded as the degree of abduction obtainable in the coronal plane, internal and external rotation were gauged in general terms. In cases with involvement of the hip joint, the degree of abduction was usually recorded by the maximal intermalleolar distance obtainable at the ankles, measured with a tape measure. The power of the hand grip was measured in some cases by a spring dynamometer, with patients who were unable to record on this instrument, the grip was measured by

left for months in unsuitable homes. In such conditions disease will certainly spread, both within the patient's thorax and also among the inmates of the house. The tuberculosis problem is thus being intensified by the spread of infection and disease to others. Sound administration leads not only to the arrest and cure of disease, but also to the prevention of disease within the patient's family.

Our emergency beds have often been used, also, for the speedy admission of urgent cases from the district, priority being given to the early acute case which cannot be nursed or treated effectively at home.

Case 7—Boy aged 16. Mass miniature radiography negative in March, 1949. Acute pneumonic disease, temperature 102°F, sputum positive, in December, 1949 (see fig 2). Visited with general practitioner on Dec 16, 1949. Admitted to hospital on Dec 17, weight then 9 st 6 lb. Excellent response to chemotherapy and later to right diaphragmatic elevation. Discharged home Feb 23, 1950, to continue bed rest and pneumoperitoneum refills. June, 1950, quiescent, up and about, weight 13 st.

Case 8—Girl aged 16. May 7, 1948, acute excavating lesions right mid zone (fig 3a). Home visited, poor conditions. May 8 admitted to hospital. Excellent response to absolute rest and right diaphragmatic elevation. Aug 21, 1948, discharged home to continue bed rest and pneumoperitoneum refills. June, 1950, disease arrested (fig 3b), in full work.

Case 9—Girl aged 19. Sputum positive, acute exudative disease with excavation in right upper and mid zones. Some disease also in left mid zone (fig 4a). Visited with general practitioner Aug 3, 1948, admitted to hospital Aug 4. Good immediate response to absolute rest and right diaphragmatic elevation. Oct 25, 1948, discharged home to continue bed rest and refills. June, 1950, disease arrested, in full work (fig 4b). Three sisters of school age have remained healthy.

With proper management and the full cooperation of the patient, immediate treatment will often bring early arrest of disease and conversion of infectivity. The above are but three of many patients who have benefited from the prompt use of emergency beds in the tuberculosis unit. The empty beds are maintained by the discharge of patients as soon as they have reached a stage when adequate care and attention can be given in their own

Fig 4—Case 9: (a) on Aug 2, 1948 (b) on Feb 21, 1950

home. Strict bed rest is then continued for the appropriate period. Total admissions to the unit in 1949 were 250.

In another group home conditions have been more favourable and have justified the institution of management and of collapse treatment in the home (Townsend, 1950). Between Sept 1, 1946, and June 30, 1949, artificial pneumothorax was induced in 70 cases, after a preliminary period of rest, in a further 19 cases pneumothorax followed diaphragmatic elevation. Some of these cases were also admitted to the tuberculosis unit for thoracoscopy and adhesion section, most of these were returned in hospital for a few weeks after thoracoscopy, and then returned home to continue bed rest. We are indebted to Mr Robert Laird, F.R.C.S., for his whole-hearted cooperation in the work of the unit.

In addition, 105 patients were treated in their homes by phrenic crush, to induce diaphragmatic relaxation, and then by pneumoperitoneum. These patients were brought to the unit by car for the phrenic crush operation, and returned home the same evening. The pneumoperitoneum was started six days later. A further group about a quarter to a third of all admissions, came in for appropriate treatment and were later transferred to sanatoria.

The prevention and cure of phthisis are clinical problems and should be clearly linked with general medicine. Tuberculosis wards in a general hospital are an essential part of sound tuberculosis administration, and lead to

efficiency both in preventive and in curative medicine. Both patients and staff in the Central Middlesex Hospital have gained immensely by collaboration with other departments of the hospital.

The tuberculosis wards are under the direct control of the physician to the Willesden Chest Clinic, additional medical staff of the combined unit are a senior registrar, a registrar, and a full-time house physician. The chest physician has direct and personal responsibility for all admissions and discharges. A thoracic surgeon visits regularly to undertake bronchoscopies, phrenic crushes, and thoracoscopies.

Delay in diagnosis is still a major problem and one that mass radiography cannot solve. Tuberculo-

Fig 3—Case 8 (a) on May 7, 1948 (b) on Feb 28, 1950

these became increasingly troublesome—particularly left hip joint—causing him much pain and difficulty in mg and also with sitting

pregnenolone therapy was started at the beginning of ember, 1949. At this time there was complete fixation e dorsal and lumbar spine, but the patient was relatively from backache. There was severe limitation of move t of both hip joints with gross impairment of internal and mal rotation and of abduction. At the right hip flexion limited to 45°, and at the left hip to 60°, from the trunk ough limitation of flexion at the hip joints, he was unable it up with his legs extended (the maximal intermalleolar ance at the ankles was unfortunately not recorded in this). Chest expansion, measured at the nipples, was m. The B.S.R. was 54 mm in 1 hour. Radiographs of e, pelvis, and hips showed the changes characteristic of ylosing spondylitis.

Pregnenolone 200 mg was given daily by intramuscular ction, with an interruption of nearly a week towards the . of November, due to an intercurrent febrile illness ogether 3 g was administered. There was gradual sub ve improvement during the period when the injections e given, and 1 week after the completion of injections, patient said he felt better than he had felt for 2 years. ectively there was definite improvement in the degree of ion of the hip joints, both could now be flexed to an angle 30° to the trunk, although internal rotation and abduction e still very limited. Chest expansion now amounted to 4 in. The B.S.R. at this period was 45 mm in 1 hour ere was no evidence of any movement in the dorsal or nbar spine.

On re-examination 4 months later, the patient said that the rovement not only had been maintained, but had further eased. He could now sit up with his legs extended, and e increased flexion of both hip joints had been maintained. S.B.S.R. was 48 mm in 1 hour.

Case 2—A girl, aged 18 years, had a history of relatively ute onset of rheumatoid arthritis in November, 1948 e was admitted to hospital on March 11, 1949, with pain d stiffness involving fingers, wrists, shoulders, and knees, d a moderate intermittent pyrexia of 99–100°F. There is no cardiac involvement and no lymphadenopathy, and e spleen could not be felt. There was no response to ocylates. Her B.S.R. averaged 80 mm in one hour. Early ay, she was started on a course of 'Mycerym,' which was pped at the end of June when a total of 0.5 g had been ven. She was then no longer pyrexial but otherwise her nical condition was substantially unchanged.

On July 22 she was started on Δ_4 pregnenol 17 β -one 3 0 mg daily by intramuscular injection. This was con ued for 1 month. No improvement took place, however, d the injections were discontinued. On Sept 1 she was arted on Δ_4 pregnenol 17 α -one 3 in doses of 100 mg aily, later increased to 200 mg daily. This compound was ntinued until Oct 13, when a total of 10.3 g had been given here had again been no significant change in her condition. Δ_4 pregnenolone injections were started on Nov 18 t this time the fingers, wrists, and knees were involved d the patient complained of pain on movement of the oulders, though the range was not restricted. Wrist and nger movements were limited, and the skin of her hands was ny to the touch. Functional capacity in the upper as reasonably good, and she could feed herself and her hair. Both knees showed appreciable synovial ening but no effusion. Extension in the left knee was d to 150°. She could just manage to walk a few steps support. X-ray examination showed typical rheumatoid ges in hands and knees, with absorption of the articular ages of the knees, especially on the left side.

Pregnenolone 200 mg was given intramuscularly ay from Nov 18 to Dec 31 (total 8.2 g), no local ions occurred. There was gradual relief of pain during nd week of treatment, and on Nov. 28, 10 days after ng pregnenolone, she walked unaided for the first time asion of the left knee was now 170°. From this time er walking rapidly improved, and by the end of December ould walk without a stick and with only a slight limp ovement had taken place in the wrists, although move s were still a little restricted and painful. Her finger s were obviously less swollen. The skin of the hands ver, remained moist to the touch. Averages of serial eadings (mm in 1 hour) for the months from June to

December were: June 82, July 66, August 76, Sept ember 59, October 59, November 46, and December 37.

She was discharged from hospital on Jan 6. Since then improvement has been maintained, and functional capacity has continued to increase despite the absence of treatment. Extension of the left knee remains limited to 170°. The B.S.R. has stayed fairly constant at 30–40 mm in 1 hour.

Case 10—In this case, that of a man aged 35, rheumatoid arthritis began fairly acutely in December, 1947, previously he had been subject to frequent attacks of tonsillitis, and his throat has continued to be somewhat sore each morning. The arthritis became worse during 1948, and in September of that year he was compelled to cease work as a potter's dipper. During 1949 he had two courses of gold therapy (total quantity unknown), with only temporary improve ment. During this period he was also experiencing epi gastric pain 2 hours after food, relieved by food and alkalis. In September, 1949, his doctor referred him to hospital with a view to tonsillectomy.

At this time there was involvement of multiple peripheral joints, with soft-tissue swelling, pain, and tenderness, wrist movements were restricted and elevation of the right shoulder was reduced by about 25°. The knees and ankles were painful on movement and the ankles were swollen, the range of movement, however, was full. A barium meal showed a chronic juxtapyloric ulcer. It was decided to postpone tonsillectomy until he had had a course of medical treatment for the ulcer.

He was admitted to a medical ward and after 5 weeks on a routine Sippy régime the ulcer could no longer be demon strated radiologically, he was discharged on Nov. 17, 1949, with a view to readmission later for tonsillectomy. During his stay in the ward there was no improvement in his joint disease, which appeared to be progressing steadily. His average B.S.R. at this period was 31 mm in 1 hour.

During December 1949, and January, 1950, the joint condition continued to deteriorate, both knees now became swollen with increasing pain and great difficulty in walking. By January his B.S.R. had risen to 60 mm in 1 hour. It was decided to include him in the more extended trial of Δ_4 pregnenolone, and at the beginning of February he was again admitted to hospital.

The condition of his joints had deteriorated appreciably since September, 1949. In particular, abduction at the right shoulder was now limited to 90° (almost wholly due to scapular movement). There was effusion in both knee joints, larger on the left (circumference of the right knee 14½ in., and of the left knee 15 in.) with limitation of flexion to 55° on the right side and 65° on the left, and of extension to 170° on the right side and 150° on the left. At each wrist the total range of move ment was limited to 80°. His grip in the right hand (dyna mo meter) was 0 kg and in the left 10 kg. He could wash and feed himself but combing his hair with the right hand was difficult. He could just walk to the toilet unaided, but with considerable pain. His average B.S.R. during the preliminary period of observation was 60 mm in 1 hour. Radiographs of his joints showed minimal changes: there was osteo porosis with early erosion of the cartilages of the wrist joints, and some osteoporosis at the interphalangeal joints. His condition did not change during the month before pregnenolone injections were started.

In the 3 days after pregnenolone therapy was started, there was appreciable symptomatic relief. At the end of a week elevation of the right shoulder was full, walking was begin ning to be easier, and finger, wrist, and knee joints appeared less swollen. This improvement continued until the 'control' injections were substituted. 1 week after these began he complained of returning pain in all joints and at the end of 2 weeks' elevation at the right shoulder was again limited to 90°. 3 days after pregnenolone injections were re started, improvement reappeared, and at the end of a week the right shoulder movements were again full. At the end of the second course of pregnenolone injections, he stated that he felt better than at any time since his arthritis had begun, his only complaint was of some pain in the feet on walking, which appeared to be due to pes planus. Movements at the right shoulder were now full. The wrists were not swollen or tender, and the range of movement was 110° on the right side and 120° on the left side. Grip (dynamometer) amounted to 50 kg on the right side and 55 kg on the left. In both knee joints effusions were still present but the circumference of each was now 14 in. and the range of movement had now

their squeezing a rubber bulb connected to a mercury manometer. The circumference of affected knee joints was also recorded. In every case measurements were made once weekly by each of us independently.

After the initial period of observation, all the patients received pregnenolone intramuscularly in an initial dose of 300 mg, followed by 200 mg daily. In the seven cases treated during the second stage of the trial this treatment was continued for 3 weeks. At the end of this period, injections of oil containing no pregnenolone were substituted, as a control. This was done without the knowledge of the patients or of the nursing staff who were giving the injections. This "control" injection was continued once daily for 2 weeks. A second period of pregnenolone injections was then started, and this time the pregnenolone was given in combination with ascorbic acid (1 g) and hyaluronidase (1000 units), all three being administered simultaneously from the same syringe. These injections were continued for a further 2 weeks.

It was decided to employ a "control" period on the same cases in the middle of the trial rather than to have a separate series of control cases, on account of the difficulty of finding strictly comparable cases in this disease, which presents a complex clinical picture. We felt that if Δ_4 pregnenolone had in fact any true cortisone-like activity, any cases which had improved during the initial treatment period should show a tendency to relapse during the control period and improve again when pregnenolone injections were resumed. Except for routine analgesics, no other therapy was employed during the trial.

RESULTS

Objective Improvement—Of the ten cases treated by intramuscular injections of Δ_4 pregnenolone, three showed significant, measurable, objective improvement. Two of these cases were treated during the preliminary trials (when no control period was employed). In one of these two cases—probably both—there is considerable doubt whether the improvement can be directly attributed to the pregnenolone therapy, for reasons which will be discussed further below. In the more extended trial, only one of the seven cases showed objective improvement. Brief case histories of these three patients are given below.

* Classification of Steinbrocker et al (1949)

† Ankylosing spondylitis

Subjective Improvement—When the more trial was begun, six of the seven cases reported immediate improvement. They all described a reduction in pain and a subjective sense of mobility in the affected joints which was marked about 1½ hours after each injection. With one exception, however, no objective could be demonstrated with the goniometer or the measure. One of the patients (case 8), who had been bedridden for 2 years, walked a few steps with help at the end of the 1st week of treatment. There was, however, no convincing objective change in any of her joints and she was unable to repeat the performance the following week despite the continuance of pregnenolone injections. Moreover, in most of the cases the subjective improvement 1½ hours after the injections continued during the period when the control injection was being used. In no instance could the sense of subjective improvement be said to amount to euphoria, even in those cases showing objective improvement.

Reviewing the period of treatment as a whole, with the exception of case 10, the enthusiasm of the patient was greatest during the first 2 weeks, and waned without obvious cause during the 3rd week of pregnenolone administration. It remained substantially the same during the period of "control" injections, and certainly there was no reawakening of enthusiasm when pregnenolone injections were resumed.

Toxic Effects—No general toxic effects were observed which could be attributed to the pregnenolone. One of the earlier cases (case 2) developed a recurrent symmetrical purpuric eruption on the legs during treatment. It was clear from the history, however, that there had been one or more similar attacks before pregnenolone was administered, and the rash disappeared spontaneously despite the continuance of treatment.

Local reactions, on the other hand, occurred in seven of the cases and were severe in five. These reactions, which appeared at the injection sites after a latent interval of 3 weeks, consisted of red, brawny, indurated swellings, which were extremely tender to touch. These swellings were very painful, and in one instance (case 8) prevented the second course of pregnenolone injections from being given. In four cases the reactions first appeared at the end of the initial 3 weeks of pregnenolone injections and tended gradually to fade during the period of control injections. It was partly for this reason that hyaluronidase was given during the second period of pregnenolone injections. It was hoped that by hastening absorption hyaluronidase would lessen the tendency to local reaction. Unfortunately it made no difference, for reactions reappeared at fresh injection sites in each of the previous reactors 1 week after injections were resumed. Sensitisation to the solvent has not been eliminated as the cause of these reactions, which would certainly constitute a serious objection to continued intramuscular administration of this compound by the method described.

CASE HISTORIES

The principal facts about each of the ten cases are shown in the table. The following are brief case histories of the three patients who showed objective improvement.

Case 1—A man, aged 27, began to have pain in the lumbar region during the summer of 1943, while he was serving in the R.A.F. Ankylosing spondylitis was first diagnosed definitely at the end of 1944 and he was then given a course of deep X-ray therapy, with considerable benefit. In October, 1945, he was discharged from the R.A.F. with a 30% disablement pension. During 1946 pain appeared in the dorsal spine, and he had a second course of deep X-ray therapy, with much relief. By the end of 1946 although his back was very stiff, all pain had gone, and early in 1947 his disability was reassessed at 20%. He remained improved during 1948 but early in 1948 his hip joints became involved and dis-

At 12 30 A.M., on May 18, the patient was admitted to the Gow Royal Maternity and Women's Hospital in an extremely shocked condition. Her pulse was imperceptible, her blood pressure 50/40. During the next two hours 500 ml of plasma and 2 pints of blood were administered. The pulse rate slowly diminished to 100, but twelve hours after admission the blood pressure was still only 70/40, though the pulse rate had dropped to 96. During the day the patient received 8 oz. of fluid. Fluid intake by mouth was satisfactory, but urinary output was very low.

Course of Illness

May 19—Her pulse rate diminished gradually to 88, but the blood pressure did not rise beyond 90/60. Despite adequate fluid intake urinary output remained low. The urine contained 2.5 parts of albumin, and the blood urea level was 141.6 mg per 100 ml. In the evening 200 ml 10% glucose and 1 litre of sodium sulphate solution were administered intravenously.

May 20—The patient was still very ill. Hiccups and nausea were troublesome, and she vomited 3 oz of fluid. The blood pressure was 90/70 and the pulse rate 70–80. Urinary output improved, but the blood urea was 162 mg per 100 ml. Hemoglobin was 7.7 g per 100 ml.

May 21—Hiccups were almost constant, and slight jaundice appeared. The blood pressure rose to 124/80, and the urinary output improved slightly. The blood urea, however, continued to rise and reached 173 mg per 100 ml.

May 22—Jaundice had deepened, and the breath was fetid. The blood pressure fell once more to 90/70, the urinary output diminished, and nausea and vomiting were again troublesome. The blood urea level remained stationary at 173 mg per 100 ml. Hemoglobin was 8.1 g per 100 ml. The urine now contained only 0.5 parts of albumin (Esbach).

May 23–25—During the next three days the clinical condition remained stationary, but the blood urea continued to rise and by May 25 had reached 210 mg per 100 ml. The plasma gave a positive immediate direct and indirect van den Bergh reaction, the icterus index was 16, and the plasma contained 7 units of bilirubin. The blood pressure rose to 107/70 and the urinary output rose once more to 16 oz.

May 26—Vomiting became more severe, the urinary output fell once more, and the patient was rather drowsy. Only a trace of albumin was present in the urine, but the blood urea was now 226 mg per 100 ml.

Fig 2—Liver (case 1) showing gross central necrosis of anoxic type. (Hæmatoxylin and eosin) ($\times 160$)

May 27—The jaundice was now lessening, but the patient was more drowsy. The blood pressure fell again to 85/50. Vomiting increased, but the urinary output was, if anything, improved. The plasma phosphatase was 15.9 units per 100 ml and the blood urea 219.6 mg per 100 ml.

May 28—The patient was very drowsy, though the blood urea had dropped to 210.8 mg per 100 ml. The urinary output rose to 18½ oz, but the blood pressure was only 80/50.

May 29—Slight nasal bleeding occurred, and the patient was much weaker. Vomiting continued, and the urinary output fell. The plasma lipid phosphorus was 12.8 mg, and the plasma amino acids 13.9 mg per 100 ml. The blood pressure was 110/70.

May 30—The patient was semiconscious, and hemorrhage occurred from nose and mouth. The pulse was poor and irregular, and at 1 35 P.M. death took place.

Fig 1 shows some of the main findings.

Necropsy Findings

The body showed well marked general pallor, and the feet and ankles were oedematous. The right side of the heart, which weighed 380 g, was full of clot resembling red-currant jelly. The left side was empty. On the wall of the left ventricle just below the aortic valve was a small sub-endocardial hemorrhage. The respiratory passages were clear, and there was no sign of inflammation. The liver was much enlarged, weighed 2400 g, and showed a general pallor. In contrast to this pallor, however, were irregular patches of subcapsular congestion over the upper surface and on the cut surface. The lobular markings were blurred, and there were numerous tiny areas of intense yellow opaque pallor which were obviously necrotic. The gall bladder was normal. No significant change was seen in the spleen, which weighed 200 g and was firm and of normal colour with distinct malpighian bodies. The kidneys (right 340 g, left 300 g) were much swollen. There was a little congestion of the stellate veins of the capsule, but the kidney substance was extremely pale. The cortical markings were very indistinct and in many places had disappeared. Numerous small superficial hemorrhages were present on the posterior surface of the uterus. These had spread along the surface of the tubes, and there was well marked hemorrhage between the layers of the broad ligament on both sides. The brain was very pale and oedematous but otherwise normal. There was no sign of damage to the pituitary gland.

Microscopical Findings

No gross abnormality was seen except in the liver and kidneys.

Liver—The hepatic parenchyma showed conspicuous changes. The cell columns were widely separated in all areas, and the cells appeared shrunken. There was no gross congestion, and the changes suggested interstitial oedema. In numerous sites there were large areas of healing necrosis involving middle and central zones of lobules, and in all other lobules there was degeneration of the cells surrounding the central vein. The necrosis was of coagulative anoxic type, and the remains of liver cells were seen. Much of the tissue, however, consisted of pigmented macrophages, fibroblasts, occasional polymorphs, and thrombus material (fig 2). Some of the necrotic areas had undergone more complete healing and the dead material had disappeared.

Fig 1—Findings in case 1

increased to flexion, right 35° and left 45°, and extension, right and left 170°. His B S R, however, remained between 60 and 70 mm in 1 hour.

He was now put on to a maintenance dose of 100 mg twice weekly, after 2 weeks he again began to complain of returning pain and stiffness, especially in the right shoulder. The dose was therefore raised to 200 mg thrice weekly, and a week later his symptoms had again disappeared.

DISCUSSION

Davison and Koets (1949) first described the use of Δ_4 pregnenolone in the treatment of ankylosing spondylitis, and they claimed favourable results. They administered the steroid intramuscularly, dissolved in a vegetable oil, as in this series. Owing to the scarcity of the drug we have been able to treat only one case of ankylosing spondylitis, and therefore do not feel able to comment on its value in this condition. Perhaps, however, it should be pointed out that our patient received altogether only 3 g, and that his improvement has not only been maintained, but has continued for several months since injections were stopped. One must, therefore, be very cautious about attributing his improvement to pregnenolone therapy.

More recently, Freeman et al (1950) have claimed beneficial effects with Δ_4 pregnenolone in the treatment of rheumatoid arthritis. They treated a series of thirty cases, administering the drug orally in an average dosage of 500 mg daily. They claim that of their thirty cases, fifteen showed major objective improvement. In our series the compound was administered parenterally in doses of 200 mg daily, and it may be questionable how far the results in the two series are comparable. In our series of nine cases of rheumatoid arthritis, however, only two showed objective improvement. It was clear from observation during the "control" period that subjective improvement could be largely discounted. Moreover, a critical examination of the history of case 2 throws some doubt on the correctness of attributing her improvement to pregnenolone therapy. Although her clinical condition had remained substantially unchanged for several months before pregnenolone therapy was begun, the monthly average value of serial B S R readings was tending to fall steadily during this period. This might well have presaged a spontaneous clinical remission which happened to coincide with therapy—a view supported by the absence of relapse when pregnenolone therapy was discontinued. On the other hand, the behaviour of case 10 strongly suggests that this patient's improvement was directly due to pregnenolone therapy. When treatment was begun he showed early subjective and objective improvement. During the period when, unknown both to him and the nursing staff, "control" injections were given, he relapsed both subjectively and objectively, and as soon as pregnenolone therapy was resumed, he improved again. Moreover, when an attempt was made later to reduce the dose, he again relapsed, and he again improved when the dose was increased. However, although his clinical improvement was certainly striking, the remission was not complete, for effusion still persisted in both knee joints and the B S R remained unchanged.

While it would be unwise to draw any dogmatic conclusion from so small a series, it seems clear that, at least with the dosage we employed, Δ_4 pregnenolone is unlikely to be widely applicable in the treatment of rheumatoid arthritis. Whether better results would be obtained with heavier dosage is uncertain. With the technique we used, it is fairly certain that local reactions would quickly prohibit any increase. If, as is claimed by Freeman et al (1950), pregnenolone is readily absorbed when given by mouth, a further trial, employing a higher dose by this route, would perhaps be worth while. Any such trial must, however, include

objective and recordable criteria for assessing therapeutic efficacy, and it should also include a "control" period, either before or during the trial.

SUMMARY

One case of ankylosing spondylitis and nine cases of rheumatoid arthritis have been treated by intramuscular injection of Δ_4 pregnenolone acetate in oil.

Objective improvement was evident in the case of ankylosing spondylitis and in two of the cases of rheumatoid arthritis. In two of these three cases, however, it is questionable whether the improvement can be attributed to the pregnenolone therapy.

Local reactions occurred in seven of the cases, and were severe in five.

Acknowledgments are due to Bengers Laboratories Ltd. for supplies of the steroid compounds used in this investigation.

ADDENDUM

Since this article was written, Guest et al (1949) have described seventeen cases of rheumatoid arthritis treated with intramuscular injections of pregnenolone. One case of rheumatoid spondylitis improved objectively and subjectively.

PUERPERAL URÆMIA DUE TO ACUTE UPPER-NEPHRON NEPHROSIS REPORT OF THREE CASES

A D T GOVAN

M B Glasg, Ph.D Birm, F.R.F.P.S.

DIRECTOR OF RESEARCH, GLASGOW ROYAL MATERNITY HOSPITAL

I MACGILLIVRAY

M.B Glasg, M.R.C.O.G.

GARDNER RESEARCH SCHOLAR, DEPARTMENT OF MIDWIFERY, GLASGOW UNIVERSITY

NOT much has been published on puerperal uræmia and it is only within recent years that a detailed clinical and pathological study of this condition has been made. Nevertheless in a short time opinions about its aetiology and pathogenesis seem to have become rather fixed. At present attention is confined to two lesions thought to cause puerperal uræmia—bilateral renal cortical necrosis and the so-called lower nephron nephrosis. Indeed, in a recent discussion on the subject at the Royal Society of Medicine (1949) it was tacitly assumed that no other lesion is even encountered.

The following cases are of interest in that they exhibit a fairly definite clinical syndrome associated with an acute lesion of the upper nephron.

FIRST CASE

Mrs A, 2 gravida, had always been well and had no history of renal or hepatic trouble or relevant family illness. In February, 1942, she had given birth to a full time female child.

In 1948, when she was 36 years old and 35 weeks pregnant she delivered herself spontaneously of a 5½ lb female infant at 10.10 P.M. on May 17. The placenta was expelled at 10.20 P.M., and the patient was given 'Pituitrin' 0.5 ml plus 'Neo Femergin' 1 ml immediately. A moderate postpartum hemorrhage occurred, and another 0.5 ml of pituitrin was given at 11 P.M. Despite this treatment the uterus remained flabby and bleeding continued, and at 11.30 P.M. Omnipon gr ½ was given.

liver—The microscopical changes were similar to those in case 1, but were obviously not of such long standing. The central and middle zones of the lobules were necrotic, in many cases only the last four or five cells of the cords adjacent to the portal tracts had been spared. The necrosis of anemic type and most advanced in the central zones, where only the "ghosts" of cells remained. In the middle the cells were rounded off and bright pink with pyknotic nuclei.

kidneys—Changes were of two main types. In the outer cortex there were many wedge shaped areas of typical cortical infarct, due to thrombosis of afferent vessels. In the centres of these areas all structures, tubules, and vessels were necrotic, but nearer the periphery the distal parts of the nephrons seemed to have survived. Mitosis was seen in the epithelium of a few tubules (fig 5). Haemoglobin and uruminoid casts were fairly common in these tubules, and few contained the ghostly outlines of red cells. The non-necrotic areas were entirely different. The glomeruli were rather large but of average cellularity. The capillaries were patent but showed the thickening typical of toxæmia of pregnancy. The proximal tubules in association with these glomeruli showed changes similar to those in case 1. Each glomerulus was surrounded by a cluster of first convoluted tubules lined by swollen hydropic epithelium, with basal pyknotic nuclei (figs 6 and 7). Some of the second convoluted tubules contained debris but were otherwise healthy. The tubules of the medulla were dilated, and many contained casts. There was severe oedema of the surrounding connective tissue. The arteries supplying the necrosed areas of the

Fig 5—Tubules at edge of necrotic area (case 2) showing mitosis and evidence of regeneration. (Haematoxylin and eosin) ($\times 600$)

outer cortex contained hyaline pink thrombus, which had obviously been present for a considerable time.

THIRD CASE

Mrs C, 7 gravida, aged 39, was admitted to Robroyston Hospital, at 10.30 P.M., on March 31, 1948, as a case of concealed accidental hæmorrhage. Her previous obstetric history was without incident. She had given birth to six full-time children, all alive and well. There was a vague history of what may have been an attack of rheumatic fever in childhood but otherwise she had always been healthy. Nothing significant was noted in her family history.

The present pregnancy had been uneventful until a month before admission to hospital, her legs and ankles became swollen. At 8 P.M. on March 31 she was seized with continuous acute abdominal pain. There was no sign of bleeding, but there was much vomiting.

On admission she was collapsed pale, and cold, with a rapid feeble pulse, gross oedema of legs and feet, and less severe generalised oedema. She still complained of abdominal pain, and her abdomen was tense. She was given morphine $\frac{1}{4}$ gr and an intravenous plasma drip was set up. 1 pint was run in. She was very restless and still complained of pain, and a further $\frac{1}{4}$ gr of morphine was given. 1 pint of blood was then given (group A2).

Course of Illness

April 1—At 12.20 A.M. there was a gush of blood and liquor. Fairly free bleeding occurred. No uterine contractions could be felt, and pituitrin 0.25 ml was given twice. At 12.55 A.M. a stillborn child was delivered, quickly followed by the

Fig 6—Glomerulus of inner cortex (case 2) surrounded by first convoluted tubules showing hydropic degeneration. Second convoluted tubules are relatively healthy. (Haematoxylin and eosin) ($\times 160$)

placenta and a large retroplacental clot. The fundus was firm, and very little bleeding took place thereafter. The patient was catheterised before bleeding occurred at 12.20 A.M. but the bladder was apparently empty. Later in the day she improved somewhat, but her general condition was still poor, with blood pressure 110/60. 1 oz of urine containing albumin and blood was obtained by catheter during the twenty-four hours. 72 oz of fluid by mouth was taken satisfactorily, but there was some sickness. In the afternoon 29 oz of 50% glucose-saline solution, plus 1 pint of 10% glucose-saline solution were given intravenously. Oedema was massive and generalised.

April 2—Only 4 oz of urine was passed, despite adequate fluids by mouth, and the general condition remained stationary. Blood pressure 120/70. Pulse rate 115.

April 3—Vomiting was now more troublesome. 5 oz of urine was passed. 2 pints of 5% sodium sulphate solution and 1 pint of 50% sucrose solution were given intravenously.

April 4—Vomiting was very frequent. A further pint of 5% sodium sulphate solution was given intravenously. 16 oz of urine was passed, but the general condition was very poor. Blood pressure 125/70. Pulse rate 60.

April 5—There was no change in the patient's condition. Vomiting continued. Urinary output fell to 12 oz.

April 6-8—Conditions remained unaltered. The urinary output remained steady at 15 oz. Vomiting was still severe and on April 8 $\frac{1}{2}$ pint of blood was administered.

April 9—The urinary output improved, $23\frac{1}{2}$ oz being voided. Vomiting continued. Blood urea 340 mg per 100 ml. Hiccup occasionally.

April 10—Further vomiting. Urinary output fell to 19 oz. Hiccup troublesome. 1 pint of 20% glucose-saline solution was given. Patient drowsy.

April 11—33 oz of urine was passed. The patient was not comatose. Late at night she had several convulsions. She died at 3.20 A.M. on April 12.

Fig 8 summarises the more important changes during her illness.

Fig 7—Hydropic epithelium (case 2). Note resemblance to Fig 3. (Haematoxylin and eosin.) ($\times 600$)

Fig 3—Renal cortex (case 1) showing hydropic degeneration of first convoluted tubules. Some of second convoluted tubules are dilated (Hæmatoxylin and eosin) ($\times 160$)

Kidneys—No abnormality was found in the glomerular tufts, which were of normal size and cellularity and with patent capillaries. In a few places the epithelium lining Bowman's capsule was swollen and pale. The greatest changes were seen in the first convoluted tubules and broad descending limbs of Henle. The epithelial cells of these tubules were grossly swollen (fig 3) and colourless, they seemed to consist of sacs of water covered by a thin film of finely granular cytoplasm. The nuclei were very small and dark. In some cells the nuclei were absent, but there was no suggestion of acute necrobiosis. Most of the second convoluted tubules (fig 3) were dilated and lined by flattened epithelium. A few contained pigmented casts. The remainder of the tubules appeared to be comparatively normal.

SECOND CASE

Mrs B, 2 gravida, aged 22, was admitted to Robroyston Hospital, Glasgow, at 6.30 p.m. on Feb 6, 1948. She had always been healthy, and there was nothing of note in her personal or family history. In 1946 she had had a normal full time pregnancy. The present pregnancy had been uneventful until two weeks before admission, when her ankles became grossly swollen. The patient then attended her doctor, but there is no note of blood pressure or urine findings. She was then 26 weeks' pregnant. During the afternoon of Feb 6, 1948, she was seized with acute continuous abdominal pain. At 5 p.m. she delivered herself of a stillborn child. A large blood-clot was passed with the placenta, which presented a well marked central depression. After delivery there was a considerable hæmorrhage.

On admission she was pale and felt cold. Her pulse rate was 100 and respirations 23 per min, but her temperature was normal. Her blood pressure was 100/40. By this time the uterus was firm and bleeding was very slight. She received 1 pint of plasma followed by 1 pint of blood and improved considerably.

Course of Illness

Feb 7—General condition poor. Further transfusion of 1 pint of blood. Blood pressure increased to 100/60. Nausea and vomiting in the evening. During the day 20 oz of urine was passed. The temperature rose to 100°F.

Feb 8—Her hæmoglobin being only 25%, a further pint of blood was given. The blood pressure by this time had risen to 120/80, but her general condition was still poor and her temperature was 100.2°F. A further 20 oz of urine was passed.

Feb 9—No improvement was shown, and only 16 oz of urine was passed. The temperature was normal or even slightly subnormal. The patient took 38 oz of fluid by mouth.

Feb 10—Sickness was once more troublesome. The blood pressure was 130/100. 56 oz of fluid was taken by mouth, but no urine was passed, and therefore a continuous intravenous drip was set up, giving 25% dextrose solution and 2½% sodium sulphate solution alternately, 1 pint of the dextrose solution and 2 pints of the sulphate were administered.

Feb 11—Only 5 oz of urine was obtained by catheterisation. 1 pint of 25% sucrose solution and 2 pints of 2½% sodium sulphate solution were given by intravenous drip during the day. There was no improvement in the patient's general condition. The blood urea was 85 mg per 100 ml and the blood pressure 150/90.

Feb 12—Oliguria persisted, and only 4½ oz of urine was passed. 22 oz of fluid was taken by mouth, and 15% glucose solution plus 2 pints of 2½% sodium sulphate solution were administered by intravenous drip. V was now severe and nausea almost constant.

Feb 13—The oliguria seemed to disappear, 16 oz of urine was passed and 20 oz of fluid was taken by mouth. V persisted and the blood urea was 304 mg per 100 ml, urea 0.57 g per 100 ml, and plasma proteins 5.9 g per 100 ml.

Feb 14—Oliguria returned, and only 6 oz of urine was obtained by catheter. The patient was very drowsy and had two fits. 200 ml of 50% dextrose solution was given intravenously. Sickness became less.

Feb 15—Only 4 oz of urine was passed, and the patient had several convulsions. Her blood urea level was 364 mg per 100 ml, and she was comatose.

Feb 16—The coma gradually deepened, and the patient's condition rapidly deteriorated. Nevertheless she passed 35 oz of urine during the day. The blood urea was 463 mg per 100 ml. Death took place early next morning.

The main findings are shown in fig 4.

Necropsy Findings

The body showed much pallor and gross œdema of the lower limbs. The heart was flabby and pale and contained a large clot in all its cavities. No other abnormality was found. There was basal congestion of both lungs, with some œdema but no sign of pneumonia. The liver was enlarged, its surface was marked by serpiginous lines of hæmorrhage enclosing irregular areas of opaque yellow tissue. Similar changes were seen on the cut surface. No abnormality was found in the spleen, and the intestinal tract appeared normal. Both kidneys were enlarged, their capsules stripped easily, leaving a smooth surface. There was general pallor, but many parts of the surface showed tiny irregular areas of congestion. On the cut surface these areas of congestion were wedge shaped. The appearances suggested patchy cortical necrosis. The remainder of the renal parenchyma was extremely pale, and the differentiation between cortex and medulla was lost. The uterus was well contracted and the endometrial surface healthy. On the peritoneal surface posteriorly there were large splashes of hæmorrhage, which however, were superficial and did not extend into the myometrium.

Microscopical Findings

Material was taken from the organs and fixed in 10% formal saline solution. The main changes were found in the liver and kidneys.

Fig 4—Findings in case 2

changes suggested a degeneration of gradual onset preceding to necrobiosis. It seems unlikely that this is directly due to the initial shock, but possibly the al degeneration was related to the subsequent tabolic changes. In case 1 at least it seems difficult to ignore the part played by hepatic necrosis. A week after the original phase of shock the patient's plasma urea an immediate direct van den Bergh reaction the plasma bilirubin was 7 mg per 100 ml, alkaline phosphatase measured 15.9 units, and the day before death the plasma amino acid nitrogen was 13.9 mg per 100 ml. It has been known for some time that liver function is much upset by severe shock (Blalock and Mason 1936, Vogel et al. 1944, Frank et al. 1946).

The renal lesion is peculiar, and the only illustration of a similar change we have found is in Bell's (1936) textbook. Bell states that this lesion is found in cases of incompatible transfusion where cast-formation is absent or insignificant. Liver damage is known to occur in some cases of mismatched transfusion, but unfortunately Bell makes no reference to the liver. There was no suggestion of incompatible transfusion in our cases. All blood for transfusion was carefully cross-matched before being administered.

It is difficult to say why renal failure should follow damage to the liver. With an organ of such complicated function the mechanism may well vary from case to case. It is noteworthy however that Beattie and Marshall (1944) have reported a considerable improvement in renal function following the administration of choline to patients with renal failure due to liver damage. Barclay and Cooke (1945) demonstrated the value of choline in a patient whose symptoms bear some resemblance to those of our cases, and experimentally Christensen (1942) has described hydropic degeneration of the convoluted tubules in some animals suffering from choline deficiency. From the report of Humphrey and Jones (1948) it seems that cases of this kind are not uncommon, and that recovery is not unusual.

SUMMARY

Three cases of puerperal renal failure following shock at parturition are described.

All three had similar signs and symptoms, which resembled those described by some workers under the term "hepatorenal syndrome".

Patchy liver necrosis and a peculiar hydropic degeneration of the first convoluted tubules of the kidney were found in all three cases. In two, however, the pathological picture was complicated by a coincidental patchy cortical necrosis.

It is suggested that the hydropic renal lesion is related to hepatic insufficiency.

The possibility of a choline deficiency should be investigated in cases of this kind.

This syndrome is not uncommon in obstetrics.

We wish to thank Dr J. Hewitt and Dr W. C. Armstrong for the facilities they have afforded us and for permission to publish these cases.

ENURESIS IN ADULTS AND ABNORMALITY OF SLEEP

ROLF STRÖM OLSEN

M.D. Wales, D.P.M.

PHYSICIAN SUPERINTENDENT, RUNWELL HOSPITAL, WICKFORD,
 ESSEX. CONSULTANT PSYCHIATRIST, SOUTHEAD ON SEA
 HOSPITALS

As far as I can ascertain, the association of enuresis with abnormally heavy sleep has received scant attention. The writer of the article on enuresis in *THE LANCET* (Disabilities series 1949) stresses heaviness of sleep in connection with bedwetting and mentions the relief obtained by taking ephedrine, but I have found no published description of the syndrome of enuresis and hypersomnia. In this preliminary communication, based on a study of cases of enuresis in adults seen since 1943, I wish to draw attention to a combination of symptoms forming a syndrome which as a rule was previously most intractable.

My attention was first drawn to this abnormality during the war when two men engaged on essential work were referred to one of my psychiatric clinics because they were constantly late at work through oversleeping. One had had lifelong severe enuresis, while the other was enuretic in a milder degree. These patients, I am sure, would not have complained of their heavy sleep if they had not come into conflict with the authorities. Unlike insomnia, excessive sleep is not unpleasant or distressing, and is hardly ever the subject of complaint by the patient. The symptom has to be elicited by careful inquiry and history taking, often from relatives, and this is probably why its association with enuresis in adults has hitherto passed unnoticed. After the discovery of these first 2 cases I obtained a history of hypersomnia in almost every case (25 out of 28).

SYMPTOMS

Since 1943, 35 cases of enuresis in adults (22 male and 13 female) have been studied at the outpatient departments of the Southend General and East Ham Memorial Hospitals. The ages of the patients ranged from sixteen to forty-one years, 8 of them were over the age of twenty-five. In the first 7 cases of the series the occurrence of hypersomnia was not investigated, and these cases will not be further considered here. Of the remaining 28 patients, 25 had hypersomnia, and 3 had no abnormality of sleep as far as could be ascertained. In all these patients the nocturnal incontinence was fairly severe, there being only 2 with a frequency of enuresis of less than once a week.

In the 25 patients with hypersomnia the symptoms were all very similar. From the psychiatric point of view these patients showed a characteristic absence of anxiety—indeed symptoms of neurosis were rarely present. They are level-headed, placid, stolid, and imperturbable—in fact often dull. The general picture is one of lowered emotional tone. As regards sleep, the usual story is that the patient on going to bed falls asleep very quickly, as a rule immediately he puts his head on the pillow. The sleep is heavy and dreamless, and very deep in the morning (unlike normal sleep, which becomes lighter at this time), these people are seldom able to hear an alarm clock or people calling them, and usually have to be shaken fairly vigorously before they wake up. One man described it as a "knockout" sleep, another stated he did not wake up at the noise of the explosion of a rocket bomb which fell near his house. One comment from a third patient was "they have to give me a good shaking, otherwise I would never wake up. I have had cold water thrown on me in the morning to wake me up." They are incontinent during this period of heavy sleep, but as a rule it does not

Fig 8—Findings in case 3

Necropsy Findings

The body was slightly obese, and had well marked striae on the lower abdomen. Edema was severe in the lower limbs, sacral region, and abdomen. Slight edema was present in the hands. The face was rather puffy. No gross abnormality was seen in the heart or great vessels. The lungs were congested at the bases, but there was no sign of inflammation. Nothing significant was seen in the stomach and intestines. The liver was much enlarged and pale. In several places there was free blood in small quantities beneath the capsule on the upper surface, and there were irregular yellow areas of obvious necrosis. The cut surface showed many similar areas of necrosis in both lobes, with rather irregular congested margins. The spleen appeared normal. The kidneys were enlarged. Many spots of hæmorrhage were seen on their surface, and there were occasional small irregular yellowish areas with congested margins. The cut surface showed a patchy congestion of the outer cortex with numerous tiny pin point areas of hæmorrhage and small wedge shaped areas of necrosis, obviously a cortical necrosis like that seen in case 2. The remainder of the kidney was extremely pale. Nothing of significance was seen in the suprarenal glands. The uterus was very like that seen in case 2. Splashes of subperitoneal hæmorrhage were present on the upper posterior surface and smaller ones on the tubes.

Microscopical Findings

Pieces of tissue were selected and fixed as before in formal saline solution. Once more the liver and kidneys were the only organs to show any significant pathological change.

Liver—Changes were like those seen in cases 1 and 2. Gross necrosis was present in the centres of many lobules.

Fig 9—Recanalised thrombosed artery in renal cortex (case 3) (Hæmatoxylin and eosin) (× 600)

The necrosis was of anæmic type, the changes being around the central veins. The cells in this area were slumped, and in many lobules they were in process of appearing. Pigmented macrophages and a few polymorphs were present.

Kidneys—The pathology of the kidneys was somewhat that seen in case 2, cortical necrosis affecting small areas of the outer cortex. This necrosis involved small groups of glomeruli and their related tubules and vessels. The marked changes were present in the renal vascular system. Many of the afferent arterioles were necrotic, and many of these were thrombosed. The thrombi were partially organised, and the vessels recanalised (fig 9). In the deeper part of the glomeruli were comparatively healthy. They were larger than normal, and the capillary walls were thickened. The related first convoluted tubules showed the changes found in case 2. The lining epithelium was hydropic, with small pyknotic nuclei. The second convoluted tubules were comparatively normal. Pigmented casts were present in the collecting tubules and ducts of Bellini. The medullary interstitial tissue was oedematous.

DISCUSSION

These three cases presented a rather similar symptom complex. It is unfortunate for our purpose that they were complicated by patchy renal cortical necrosis, but according to all observers (Duff and More 1941) cases of cortical necrosis are remarkable in that the patient recovers from their immediate shock and remains symptom free, apart from oliguria, until the later stages of renal failure. None of the present patients recovered completely from the shock phase. All remained apathetic. Nausea, vomiting, and hiccups developed early in the course of their illness and remained troublesome throughout. Edema appeared or, if already present, became worse. Oliguria was constant but varied in degree from day to day, and despite increasing azotæmia the urine remained dilute and contained only a small percentage of urea. Similarly, albuminuria diminished though uræmia increased. The patients became drowsy and in the first case there were hæmorrhages from the mucosæ.

The course of the illness in these patients is rather reminiscent of that described by Heyd (1924) in reference to some cases of "liver" death following surgery of the biliary tract. Pytel (1937), in a review of this condition, described a hepatorenal group characterised by a sudden rise in temperature, rapid pulse, nausea, and vomiting. Oliguria appears, and the urine contains albumin, red cells, and casts. The urinary urea is low despite increasing azotæmia. Edema is common and may become gross. The patient becomes drowsy, and hæmorrhages may occur from the mucosæ. Boyce and McFettr (1935) described a similar group without the initial rise in temperature, and their description would fit the cases reported here. Most of the cases described have been associated with surgery of the biliary tract, but Pytel (1937), Dérot (1937), and Wilensky (1939) have described a similar syndrome following non surgical liver damage due to various causes. In obstetrics it has been described as a complication of abortion (Balard 1937, Parai 1936). Humphrey and Jones (1948) have described cases of oliguria following abortion, and the symptoms were almost identical with those of our patients. In all of their patients recovered, and these workers attributed the condition to a lesion of the lower nephron.

There was gross hepatic necrosis in all three of our cases, and the appearances suggested that the necrosis dated from the original phase of shock. Davidson (1946) has described focal necrosis of the liver in cases of extremely low blood pressure. Similarly in cases 1 and 3 the cortical necrosis was advanced and was probably related to the shock phase. In many areas there was evidence of healing (figs 5 and 9). On the other hand, in all the proximal tubules of case 1, and in all of cases 2 and 3 not affected by the cortical necrosis,

lasted for 10 months. She became regularly incontinent. The nurse stated that she slept very heavily and had to be shaken every morning as she did not hear the other patients waking up or talking. Before the operation she had never been a heavy sleeper or incontinent. For the last 8 months the normal sleep and the incontinence have responded extremely well to amphetamine at night.

It is difficult to obtain a very clear picture of the physiological mechanisms of sleep and micturition, since much of the evidence is confusing. It seems to me, however, to be established that interruption of the cortical pathways to the lower centres, particularly the hypothalamus, is important in bringing about deep sleep and loss of control of the bladder. In cases where other methods of treatment had failed, and where there was no obvious psychogenic factor, it seems likely that the pathogenesis of the syndrome of hypersomnia and nocturnal enuresis is to be sought in some functional interruption of cortical impulses to the hypothalamus and other lower centres, and that this is alleviated by the action of amphetamine. One can only speculate on where the actual fault lies, probably in some inborn error in the physiology of the cortical neurones.

SUMMARY

1 Of 28 adults suffering from nocturnal enuresis 25 have a history of excessively heavy and prolonged sleep with difficulty in waking up.

2 The patients showed an absence of anxiety and were free from neurotic symptoms.

3 The response of these patients to the administration of amphetamine sulphate at night was strikingly favourable. Failure to respond was often due to insufficient dosage.

4 These patients were not kept awake at night by the administration of amphetamine.

5 The pathogenesis of the syndrome of nocturnal enuresis with hypersomnia is discussed.

EXCRETION OF POTASSIUM AFTER PARTIAL GASTRECTOMY

A W WILKINSON
 Ch.M. Edin., F.R.C.S.E.
 GABRIELLA NAGY
 B.Sc. Lond.

BARBARA H BILLING
 B.A. Camb., Ph.D. Edin.
 C P STEWART
 M.Sc. Durh., Ph.D. Edin.

From the Department of Surgery in the University of Edinburgh, and the Clinical Laboratory, Royal Infirmary, Edinburgh.

In previous reports (Wilkinson et al 1949, 1950) we have considered the changes in metabolism of chloride, sodium, and nitrogen after surgical operations such as partial gastrectomy. Cuthbertson (1936) found, in patients after injuries to bone, that there was an increase in the excretion of potassium and phosphorus which though less than the increase in the excretion of nitrogen and sulphur was related to it in time; he also found that the excretion of sodium was little changed. From these and other observations he concluded that the increased urinary excretion of nitrogen, sulphur, phosphorus, and potassium after injury was due to the catabolism of tissue, probably muscle. Howard et al (1946) have reported that, contrary to these findings, the relationship between the quantities of nitrogen and of potassium, sulphur, and phosphorus is not exactly that to be expected

if all the excess of these substances came from the same tissue source—e.g., catabolised muscle—and that the relationship does not hold in time, the greatest output of potassium coming in the first twenty-four hours. Blaxter and Møller (1949) also found that the greatest amount of potassium was excreted in the first twenty-four hours after operation, and he attributed the loss of potassium chiefly to intracellular dehydration.

Disturbances of metabolism of potassium during the immediate postoperative period might have an important bearing on the interpretation of the previously reported retention of chloride, sodium, and water (Wilkinson et al 1949). In view of these conflicting reports about changes in postoperative urinary excretion of potassium it seemed advisable to include observations on potassium excretion in our metabolic studies.

METHODS

Five male patients were chosen who had duodenal ulcers and were to undergo partial gastrectomy.

The nitrogen balance was studied in each case. In addition, the intake of chloride and of sodium was controlled before and after operation, and that of potassium was measured though not kept at any predetermined level. The quantities of chloride, sodium, and potassium ingested daily were estimated from the tables of McCance and Widdowson (1946), check chemical analyses being made from time to time. Urine, faeces, and gastric aspirations were collected according to the method already described (Wilkinson et al 1949). Potassium was estimated by the platinum chloride microtitration method of Shohl and Bennet (1928), determining potassium as the iodoplatinate as described by Peters and Van Slyke (1932).

Analyses of certain foods by this method gave figures some 25% lower than those reported by McCance and Widdowson (1946)—e.g., milk 119.5 mg against 160 mg per 100 ml. This may be due to an actual difference in foods analysed by ourselves and these workers, or it may be due to an incomplete recovery of potassium in our analysis. We do not think that the latter alternative is the explanation, since recovery of added potassium was invariably satisfactory (95%). A similar variation between the calculated and analysed potassium content of diets was reported by Howard and Bigham (1945).

RESULTS

Before operation, on an intake of about 3 g of potassium a day, there was a small positive balance. After operation the potassium intake was nil for 1–4 days and was then gradually restored to the preoperative level, which was regained in 4–7 days after operation. For 1–3 days after operation the daily total quantity of potassium excreted in the urine rose above the preoperative level in spite of the absence of any intake, but this was succeeded by 5 or 6 days when the daily excretion of potassium was reduced in spite of the resumption of intake. On about the 7th or 8th day after operation both intake and urinary excretion of potassium had returned to the preoperative level. There were thus 3 or 4 days immediately after operation when potassium was apparently lost from the body, followed by 4 or 5 days when potassium was retained. Even if the estimates of the quantities of potassium ingested, as calculated from the tables of McCance and Widdowson (1946), were too high, the figures corrected for this possible error still indicated a retention of potassium for several days after the 5th postoperative day.

In two cases daily determinations were made of the urinary phosphorus and sulphur as well as of potassium and nitrogen. It was noteworthy that the excretions of potassium and of phosphate followed a parallel course, as did those of nitrogen and of sulphur.

disturb them and when they wake in the morning they find the bed wet

TREATMENT

For a long time belladonna and ephedrine were the standard drugs used, but it is now generally agreed that amphetamine or 'Dexedrine' give the best results, in children as well as adults. This certainly has been my experience with these adult patients. The effect is not only to reduce or abolish the incontinence but also to make the sleep more normal. A striking feature common to all these patients has been the extraordinary tolerance of amphetamine—a dose which would keep a normal person awake all night would have no effect on their sleep, and even with very large doses they sleep well, some patients report a good night's rest after amphetamine 25–30 mg taken at bedtime. Some tend at times to wake up at 2 or 3 o'clock in the morning, when they use the opportunity to empty the bladder, on going to bed again they fall asleep immediately. The usual effect, however, is for patients to wake more readily in the morning. I have not heard any patient complain of sleeplessness due to amphetamine, and if it is to have the desired therapeutic effect it often has to be pushed. Failures are in my opinion due to insufficient dosage. With some patients 10 mg at night may be sufficient, others require at least 30 mg. The dose is taken when the patient goes to bed after having emptied the bladder.

Side effects were so trivial that they could almost be ignored. In one case flatulent distension was the subject of complaint, in another a feeling of heat and excessive perspiration was noticed on waking in the morning, and a few patients have felt some dryness of the mouth.

CASE HISTORIES

Case 1—A married man, aged 32, a railway platelayer, had been a lifelong enuretic 5–7 times a week, he also suffered from hypersomnia. He stated 'I am a very heavy sleeper, they have to shake me, or I would sleep on.' A dose of amphetamine 10 mg at night had little effect on either symptom nor did 15 mg. The dose was increased to 25 mg on going to bed, the patient slept well, and the enuresis was reduced to once a week during 4 weeks. At the end of the fourth week he ran out of tablets, and in the next 7 days wetted the bed six times and slept extremely heavily. For the next 6 weeks he took 30 mg nightly, with excellent results. On this dosage he sleeps quite soundly but wakes more readily in the morning than he does by nature. He was incontinent only twice during this period, once after not taking the tablets. A month later the condition remained very satisfactory, he had been incontinent only once. He is still being followed up.

Case 2—A girl aged 20, single, a comptometer operator, who had been a lifelong enuretic, came to the psychiatric clinic complaining of bedwetting on an average three times a week. She had tried various treatments, including psychotherapy, without effect. She admitted on inquiry that she was a very heavy sleeper, her relatives had to wake her, or she would sleep on until very late in the morning. She never remembered having dreams. She was put on amphetamine 5 mg at bedtime, and the following week on 7.5 mg. A week later she reported having wetted the bed twice. The dose was then increased to 10 mg at night, and during the following 3 weeks had enuresis only once a week. The dose was then increased to 15 mg, during 10 weeks she reported no enuresis. By now she was sleeping much more lightly and often used to wake at 2 A.M. though she would have no difficulty in going to sleep again after having emptied her bladder. She has not returned to the clinic.

Case 3—A married man aged 26, a clerk, had been an enuretic since the age of 12, on his first attendance at the clinic he reported having been treated with psychotherapy, phenobarbitone, and ephedrine without effect. The bladder had been examined 8 years before, but nothing abnormal had been found. He gave a history of excessively deep sleep at night, and also stated 'I can sleep any time and any where.' He would dream at times. Enuresis varied from once to seven times a week, but usually occurred every night. After 3 weeks he had been worked up to amphetamine 12.5

mg at night and had improved considerably. He was put on 15 mg at night and did not return to the department for 3 months. During that period he had further improvement. Sleep was lighter, and became reduced to once a fortnight. Unfortunately we have sight of him.

Case 4—A man, aged 26, single, a motor attendant the psychiatric outpatient clinic for lifelong enuresis. No treatment had had any lasting effect on him and when interviewed he gave a history of incontinence varying from once a fortnight to four times a week. He was quiet and placid, giving no evidence of any neurotic symptoms and was a very heavy sleeper, nothing would disturb his rest and he could not spontaneously wake up early enough. It took him a long time to feel wide awake. He was at first put on amphetamine 10 mg, and this had some effect. After 8 weeks he had had incontinence on three occasions, but still he was rather sleepy in the morning. He continued on this dose for another 10 weeks and was then put on 20 mg at night. After 8 weeks this dose usually caused him to wake up during the night, when he micturated and immediately fell asleep again. His sleep was now not so heavy in the morning. During this period there was no incontinence but he started to complain of flatulent distension. The dose was reduced to 10 mg, and over a period of 9 weeks he was twice incontinent and his sleep was a little more heavy. He was finally stabilised on amphetamine 15 mg, at night, which did not cause any gastric discomfort. When last seen the sleep was more normal and there was no evidence of any enuresis. He failed to return to the clinic.

These are four typical examples. The other cases had a very similar history and the effect of amphetamine has been in every case extremely encouraging—almost specific. These patients have not been followed up long enough for a final conclusion to be reached, but sufficient time has elapsed for me to be convinced that amphetamine has had a striking therapeutic result provided one is not too timid in increasing the dose at night. From the cases described it will be seen that large doses are often necessary to effect cure or relief. No detrimental effects were seen.

DISCUSSION

The lateral and possibly the posterior hypothalamic areas are known to be associated with both the sleep waking mechanism and the mechanism of micturition. According to Kleitman (1929) sleep is brought about by a functional break between the cortex and the brain stem, particularly the hypothalamus, this break is due, he thinks, to a great decrease in the number of afferent impulses from the sensorium. Russell Brain (1939) considered that no part of the normal nervous system acts in isolation in bringing on sleep, but that normal sleep is the outcome of interplay between the cortex and the hypothalamic sleep waking centre. Ranson et al (1935) found that stimulation of the hypothalamic region causes contraction of the bladder. Cortical lesions, especially those which are bilateral, induce signs of release of the bladder reflexes and an increase in the response to stretch (Miller 1942). Denslow, Brown and Robertson (1933) maintain that the control of the bladder consists in the inhibition of spinal reflexes. The action of the hypothalamic centre for micturition are dependent on the intact motor cortical fibres descending through the internal capsule (Beattie and Kerr 1936). Lesions situated between the sensorium and the floor of the third ventricle cause hypersomnia and it is well known that subcortical tumours in the frontal region may cause both incontinence and excessive sleep. After the operation of prefrontal leucotomy the combination of drowsiness, heavy sleep, and incontinence of urine is common during the first week or two, this condition usually clears up, but persists in some cases.

Case 5—A woman, aged 63, was leucotomized in May, 1947. After the operation she was dull, torpid, apathetic, and incontinent. She left hospital in August, 1948, but returned in November 1948, in a neglected and apathetic state lacking spontaneity, she would often wet the bed. This condition

the quantities involved are of the order which the othesis suggests. In the experiments reported here excretion of potassium during the 3 important days amounts to about 6 g, which indicates a transfer from intracellular to extracellular compartments of about litres of fluid containing 200 mg of potassium per ml.

Further precise measurements are needed to establish the hypothesis (or to refute it), but it is perhaps worth noting out that it is consistent with various clinical observations.

Thus, during the postoperative period not only does fluid accumulate in the inflammatory area but also there is a greater tendency than usual towards retention of water, sodium, and chloride, a tendency which, when a normal saline solution is given, may lead to the appearance of generalised oedema. Whether or not oedema is usually observed in such circumstances depends on various factors: the renal efficiency with respect to the retention of salt and water, the state of nutrition and the acid-base balance, and the volume of saline given. The fact that oedema does occasionally develop is important, as also is the fact that further administration of saline worsens the condition rather than improves it: both facts point to the existence of an intracellular depletion of water and potassium. Also suggestive is the clinical impression that improvement of an established postoperative oedema may be initiated when infusion fluids contain potassium as well as sodium salts.

Similar changes in the excretion of potassium, sodium, chloride, and water after gastrointestinal haemorrhage, with or without closely associated surgical operations, have been observed by Borst and others. Borst (1948) has explained these changes as being due to a regulating mechanism which maintains a normal cardiac output. In their own patients the cardiac output was not measured, but, as judged on clinical grounds, the circulatory state of all these patients was good, except for short periods during operation and for a few hours immediately after it. We have not found any published reports of combined observations on cardiac output and renal excretion after major operations in man. It may well be that an increase in cardiac output is a consequence of retention of chloride and sodium, but if this were so it would not explain the electrolyte disturbance itself. On the other hand, it seems equally possible to relate changes in cardiac output, if they do in fact occur, with the inflammatory reaction in the injured regions.

It is a corollary of the hypothesis we have advanced that determinations of urinary chloride afford no reliable guide to the requirements of salt and water during the immediate postoperative period, excellent though they are in other circumstances. The retention of sodium and chloride after surgical operation (and probably also in other conditions associated with acute inflammation), as part of a general disturbance of water and electrolyte involving intracellular fluid, leads to a decreased urinary excretion of chloride at a time when, in fact, the extracellular fluid is increased in volume and its chloride concentration is not lowered.

SUMMARY

The urinary excretion of potassium was measured in five patients after partial gastrectomy.

In spite of the cessation of potassium intake for 3 to 5 days after operation, the urinary excretion of potassium was increased; this was succeeded by a period of 5 or 6 days when the daily excretion was reduced though the intake of potassium had been resumed.

The relationship of these observations to the previously recorded changes in metabolism of chloride, sodium, and nitrogen is discussed. A hypothesis is advanced to explain these changes in terms of the inflammatory reaction.

We wish to thank Sir James Learmonth for providing clinical facilities and for his continued interest in the work; the dietitians who provided the controlled diets, and the nurses, without whose co-operation these studies would have been impossible. A grant was made to one of us (C. P. S.) by the Medical Research Council for technical assistance and materials, and one of us (A. W. W.) has held the Syme Surgical Fellowship of this University during the course of these studies.

Reviews of Books

Research in Medical Science

Edited by DAVID E. GREEN, PH.D. and W. EUGENE KNOX, M.D. New York and London: Macmillan, 1950. Pp. 492. 48s.

MEDICINE nowadays lives at close quarters with other sciences, and draws constantly on their findings. This book has been compiled by a team of authorities in these other fields, nearly all of professional standing, and most of them American, though there are contributions from England, Australia, and Argentina. Many of the contributors are clinicians, for as the editors say in their introduction, "a new breed of hybrid investigators has arisen which includes both the clinician who has become an expert in one of the fundamental sciences, and the representative of the fundamental sciences who has become an expert in some phase of medicine." Such hybrids are Prof. Lancelot Hogben, F.R.S., who writes here incisively of the methodology of medical genetics, Dr. John Peters, professor of internal medicine at Yale, who describes 'differentiation and specialisation of biologic media,' Prof. F. M. Burnet, F.R.S., who contributes an article on viruses, and the team of three professors, two of them doctors of philosophy and one a doctor of medicine, who discuss the rôle of hepatorenal vasotropic principles in experimental shock. The book is intended for medical students who contemplate research, clinicians who are not fully aware of advances in the fundamental disciplines, biochemists who have lost touch with disease processes, and intelligent laymen. The last and perhaps even the first may think, as they ruffle the pages, that such a book is not for them: there are chemical and mathematical formulæ, awkward terms, and a froth of references left in the wake of every chapter. They will be wrong. Wherever they open and read they will be astonished to find the language clear, the principles well set out, the message comprehensible. This is an achievement on which the editors and their contributors must all be congratulated. Human nature being what it is, it is inevitable that with over thirty fine fish in the basket the glutton should still yearn for the few that got away. The editors tell us that several important subjects including sex hormones, penicillin, and neurophysiology, are omitted because several pledged contributors failed to find time to prepare their manuscripts. Perhaps these call for different angling tactics. If the editors find, when a new edition is in preparation, that tickling will not serve they should reach for the gaff.

Hémoglobine et pigments apparentes

HENRI BÉNARD, professor in the Faculty of Medicine, Paris. A. GADJOS and M. TISSIER, chefs de laboratoire. Paris: Masson, 1949. Pp. 350. Fr. 1350.

THE biochemistry of hæmoglobin and its relations has recently been much more thoroughly set out in the monograph of Lemberg and Legge, but this French book is better on the clinical side. References are given

POTASSIUM AND NITROGEN BALANCES IN FIVE CASES BEFORE AND AFTER OPERATION

Case no	Greatest loss of potassium in one day (g)	Day of greatest urinary excretion		Duration of loss of potassium (days)	Quantity of potassium lost (g)	Av daily urinary excretion of potassium (g)		Av urinary vol per day preoperative (ml)	Urinary vol on day of greatest potassium excretion (ml)
		Potassium *	Nitrogen *			In control preoperative period	In critical period of 2 immediately postoperative days		
1	2.5	0+1	0+1	2	4.47	2.18	2.43	2200	1080

* 0 = day of operation

± = variable no. of days in each case when there was no potassium diuresis

The results of the five cases are summarised in the accompanying table, and the figure shows diagrammatically the general time relationships between the intake of potassium and the urinary excretion of potassium, as well as between the disturbance of metabolism of nitrogen and that of potassium.

DISCUSSION

The increase in the urinary excretion of potassium which, in spite of a reduction in the potassium intake and in the volume of urine, occurs on the day of operation and the immediately succeeding days is in sharp contrast to the coincident decrease in the urinary excretion of sodium and chloride which occurs in spite of an increase in the intake of these ions. The changes in the electrolyte balance seem to be mutually related in that they are all parts of a general disturbance involving many chemical equilibria.

The classical observations of Benedict and of Garbile on the effects of starvation on the urinary excretion of nitrogen and potassium indicated that the losses of both nitrogen and potassium were quantitatively related: for each gramme of nitrogen lost there was a loss of about 2.5 milliequivalents of potassium, or about 1 g. of potassium for each 10 g. of nitrogen. These ratios are very similar to the quantities of nitrogen and potassium found in normal muscle.

The widespread nature of the electrolyte changes is in itself evidence against the simple view that, in the immediate postoperative period, there is destruction of tissue (for the sake, perhaps, of protein components, extra katabolism of which is shown by the increased nitrogen excretion) with the liberation of potassium from the destroyed cells and consequent excessive excretion of potassium. The time relationships also do not support this interpretation, for the increase in potassium excretion begins on the day of operation—within 8 hours of the operation according to Blixenkrone-Møller (1949)—whereas the increase in nitrogen excretion is appreciable only later. Further, the greatest excretions of potassium and nitrogen do not coincide in time. It is possible that some of the extra urinary potassium is derived from destroyed cells, or is associated with protein katabolism (since the cellular proteins exist largely as anions in equilibrium with potassium cations), but, if so, there must be some other metabolic disturbance which is probably the prime cause of the fluctuations in potassium excretion.

It might be thought that the renal conservation of potassium after injury is less successful than that of

sodium or chloride. During the immediate postoperative period not only is there an increase in the amount of potassium excreted, but also, since the excretion of water is diminished at this time, the urinary concentration of potassium is greater than before operation. This, coinciding with cessation of intake of potassium, suggests that the kidney is struggling to remove an excess of potassium rather than failing to conserve a depleted supply. The most likely endogenous source of the temporary excess of potassium is the intracellular fluid. In the early hours after injury an inflammatory exudate is formed in the damaged tissues. It may be supposed that for the provision of this exudate there is an acute demand for a fluid containing protein and electrolytes. This demand is satisfied primarily from the plasma, and thus must lead to the withdrawal of extracellular fluid from uninjured areas. Such withdrawal of extracellular fluid would in turn cause a widespread disturbance in the extracellular-intracellular fluid balance in the uninjured tissues, causing the transference of water from the cells to their surroundings. To restore the osmotic balance electrolytes must also leave the cells along with this water, a chief intracellular cation is potassium. This would lead to an increase in the potassium concentration in the extracellular fluid, and, as part of the general readjustment, potassium must be passed on from the extracellular fluid to the plasma. The end result would be an increased renal excretion of potassium, derived ultimately from normal tissue cells via the extracellular fluid and the plasma.

The hypothesis of an inflammatory reaction in the damaged tissues leading to depletion of intracellular water and salt—and it is as yet no more than a hypothesis—explains the observed increase in potassium excretion. It is also consistent with the coincident retention of water, sodium, and chloride, since the changes in the inflammatory area are followed by a demand for increased extracellular extravascular fluid, a demand which is met partly by withdrawal of fluid from the cells elsewhere and partly from saline solution given intravenously. Disturbance of the intracellular fluid is suggested by the increased urinary excretion of phosphate at the same time as the excessive loss of potassium.

Average nitrogen and potassium balances in five cases before and after operation

THE LANCET

LONDON SATURDAY, JULY 22, 1950

Frustration

In the last few years of swift change, each annual representative meeting of the British Medical Association has had a mood and tempo of its own. At this year's meeting, which ended last Monday, the mood was mixed and the tempo uncertain.

Remuneration, which has loomed large at earlier meetings, took up little time, representatives agreeing without demur—though without obvious enthusiasm—Dr WAND's proposal that they should support a decision to proceed with plans for general practitioners to withdraw from the service.¹ The General Medical Services Committee is seeking to get the better of a factor raised from 40% to 70%—a claim involving additional £7 million or so. If this claim succeeds, extra money might be used partly to reduce the maximum size of lists while keeping the present maximum income steady. Such a reduction is very desirable, but it would do little to help practitioners in "over-doctored" areas, some of whom have fallen hard times since 1948. Their need calls still—in fact, more than ever—for "loading" of the capitation on the first 1000 or 1500 patients. Those who are negotiating for the extra money which would make these adjustments possible will evidently do their best to end the open dispute implied by notice of withdrawal, but the dispute would almost certainly be referred to compulsory arbitration, which offers small chance of advantage. At the meeting (which is reported on another page), Dr J. C. ARTHUR declared: "Compulsory arbitration would be most dangerous to us." The Ministry of Health—and the Treasury—will have to be convinced by negotiation.

More attention was paid at the meeting to the status and work of the practitioner. Here the sense of frustration—a word which recurred throughout the debates—was reflected in recurrent, and sometimes pointless, defiance of the platform, in demands for a larger share by practitioners in the administration of the service, and in the enumeration of various shortcomings ascribed to the National Health Service but often dating back much further than the last two years. Clearly most minds were painfully occupied with thoughts of the falling prestige of the practitioner, so much was implicit in discussion of topics ranging from remuneration to free change of doctor and clinical assistantships.

Some at least were alive to the relation between the doctor's prestige and the work he does, and one speaker was probably expressing the thoughts of others in declaring that "unless something is done soon to support the general practitioner service, it will be too late." Among the constructive proposals were some for freer access to diagnostic resources, for closer integration between practitioner and hospital, and for an overall review of the whole service. Dr GEOFFREY BARBER mentioned that here and there teams of practitioners in groups of six or so have lately acquired premises and

set up in group practice, gaining advantages in accommodation, ancillary help and leisure. He commended this initiative to others. The chairman of the council made it clear that he thought nothing of such makeshift devices. His faith is still in experiment with health centres. But if there are grounds for believing that the promotion of group practice is an indispensable element in restoring general practice, can we wait for these centres? Blueprints offer no present comfort. Addressing the section of preventive medicine on Tuesday, Prof J. M. MACKINTOSH remarked that plans for health centres were breaking on the rock of financial competition. He would like to see salaries replace payment by number of patients or items of service, for doctors should practise in team and not as rivals. Sir SHELDON DUDLEY spoke in the same sense, and they were not contradicted.

The representative meeting was made no less uneasy by the systematic lobbying which accompanied it. Lately the association had wisely put an end to the practice of block elections to the council—a system which sometimes worked unfairly and was associated with much lobbying. One evil has been replaced by another. Organised lobbying about issues before the representative body is something new in British medical politics. This body is composed of men and women who attend, not of their own right, but as the mouthpieces of their local divisions, which have previously ranged over the principal items on the agenda. Usually these representatives are free to vote against their divisions' instructions—if they were not, the business might as well be conducted by card polls—but this is after a free and open interchange of views. In answering the whip of any separate group or sect a representative exposes himself to the risk of prejudging an issue which should rightly be settled only in the light of local and national opinion. It is, of course, for the divisions themselves to decide whether they want their representatives to be twice briefed, but this development seems strangely at variance with the freedom which some doctors profess as their aim.

Diphtheria in the Inoculated

THE medical student of today must think himself fortunate if he sees a single case of clinical diphtheria during his training. The incidence has fallen steadily from its pre-war level of around 60,000 per annum to 1897 (corrected figure) cases last year, and for this the national campaign of immunisation inaugurated in 1940 is largely responsible. Yet those charged with the immunising of children have usually been careful not to claim that the inoculations will give complete protection against diphtheria, even though their prophylactic reagents have reached a high degree of antigenic efficiency. According to estimates based on notifications, the incidence of diphtheria in uninoculated children is three to five times greater than in the inoculated, but sometimes the infection spreads through a community which has apparently been efficiently immunised. Outbreaks of this kind have been seen in boarding-schools, where the "velocity of infection" may be considered high, but that they may also occur in larger communities is demonstrated in the detailed account of diphtheria during the war years on Tyneside and in Dundee by Sir PERCIVAL HARTLEY, Prof W. J. TULLOCH, and their colleagues,

at the ends of the chapters, and this is just as well since, by an odd mischance, the letter L has been omitted from both author and subject indexes. The book is a very clear description of the clinical and biochemical aspects of the subject, and the literature is thoroughly discussed.

Hemorrhagic Disorders

PAUL M. AGGELER, assistant clinical professor of medicine, University of California, S. P. LUOMA, professor of medicine in the university, Chicago University of Chicago Press London Cambridge University Press 1949 Pp 112 £3 15s

In the past few years the fashion has grown up for arranging in book form the text, diagrams, and illustrations originally planned as an exhibit for showing at a conference or for teaching. Such exhibits generally make unsatisfactory books, and the volume under review is no exception to the common rule. The illustrations, primarily designed as "visual aids," are elementary to the point of absurdity—e.g., the jolly picture of a young woman biting herself to produce "purpura facititia." The human figure, when it appears, is luridly coloured, and only extreme forms of disease seem to be illustrated. Nor is the text very good. Some sections are perfectly sound, for instance, the authors are not deceived by recent talk about the need for finding changes in the megakaryocytes in thrombocytopenic purpura, and there is a refreshingly frank section on the treatment of hemorrhagic disease. But on the whole we doubt whether "practising physicians, medical students, and laboratory technicians" really need this sort of strip-cartoon teaching.

The Actinomycetes

Their Nature, Occurrence, Activities, and Importance SELMAN A. WAKSMAN, PH.D., professor of microbiology, Rutgers University, Waltham, Mass. *Chronica Botanica* Co London W. Dawson & Sons 1950 Pp 221 \$5

THE actinomycetes, a heterogeneous group comprising many thousands of species, are found in soil (in which they may represent nearly a quarter of the cultivable micro-organisms), in dust, fresh water, and lake bottoms, in decaying plant and animal residues, and on vegetation. They play a vital part in the processes of nature but they are also agents of spoilage and destruction of perishable materials. A few species belonging to the genera actinomycetes and nocardia are pathogenic for man and animals, and some species of streptomyces cause disease of plants, notably potato scab.

At the moment, the main interest in the actinomycetes is focused on the production of antibiotics, chiefly by species of streptomyces. About 30 antibiotics have already been isolated, and though some have proved too toxic for therapeutic use, such others as streptomycin, 'Aureomycin,' and 'Chloromycetin' are very valuable, and the prospects for further discoveries are good. Professor Waksman conducts his readers over the whole field of the microbiology of the actinomycetes—morphology and life-cycle, metabolism, growth, and nutrition. Mutation and variation, both morphological and physiological, are exhibited to a greater extent by the actinomycetes than by any other group of micro-organisms. The vexed question of taxonomy and nomenclature receives much attention and the basis of classification is fully discussed. Keys to 15 different systems of classification are given, including that of Waksman and Henrici which has already won wide approval. Of particular importance are the chapters on the production of enzymes and vitamins, the antagonistic properties of some species towards other micro-organisms, the production of antibiotics, the distribution of the species in nature, and their rôle in the decomposition of animal and vegetable residues. Separate chapters are devoted to the pathogenic species affecting animals and plants, and the final chapter is a summary of the whole work. An appendix gives the formulæ of 26 culture media, a bibliography of 522 titles, a general index, and an index of organisms.

This work should appeal strongly not only to microbiologists and biochemists but to members of every branch of medicine and even to the lay reader.

Tooth Size and Occlusion in Twins

ANDERS LUNDSTRÖM, from the State Institute of Genetics and Race Biology, Uppsala 'Basle S' 1948 Pp 206

THIS book describes an investigation which Lundström undertook in an attempt to elucidate the aetiology of malocclusion of the teeth. Among the 202 like-twin pairs investigated (100 pairs of which were diagnosed as identical), he found "considerable" malocclusion more or less equally often in both types of twins, but the identical-twin pairs had both affected rather more often than the fraternal. However, as these were relatively moderate deviations from what is regarded as normal occlusion, the value of the investigation probably lies in the metrical aspects of tooth size and spacing, and in shape of the jaws. The measurements of these characters have been carefully made, and the technique of measuring is fully and clearly described in the book. In the statistical analysis of his data, the author has followed Dahlberg's technique of partitioning variation into that due to hereditary factors, and due to non-hereditary factors. This method of analysis has certain limitations because it assumes that heredity and environment have independent additive effects. It takes no account of the fact that, because of their identical genetic make-up, monozygotic twins will respond in similar fashion to the same environment. Lundström, however, draws no more rigorous conclusion from his analysis than that, on the whole, the part played by genetic factors in tooth and jaw development is as important as that of environmental factors.

Blood Clotting and Allied Problems (New York)

Josiah Macy, Jr., Foundation 1949 Pp 231 \$2.25—Edited by Joseph E. Flynn, these conference transactions are useful not only for the original papers but also for the subsequent discussions, which are reported verbatim. Conflicting views thus come into prominence and an informative note of asperity sounds quite often. The most useful parts of this volume are the general discussion on the standardisation of thromboplastin, and a paper by Quick on the status of platelets. The other sections are more technical. So much work is now in progress on this subject that much of the material reported at this conference, held over 12 months ago, is out of date, and some of the disputants have already changed their views.

Spezielle chirurgische Therapie (2nd ed. Berne) Huber 1949 Pp 1101 Sw fr 88.—The second edition of Max Sargesser's surgery has been extensively revised and has additions too numerous to specify. It is really an excellent textbook of operative surgery. It is simple and practical in its instructions and obviously is an account of surgical methods actually practised in the University of Berne. It does not pretend to be comprehensive and includes all operations and modifications which have been described. It is up to date and can be recommended as a reliable guide to the general surgeon, and particularly to those whose experience is not great. The illustrations, which are numerous, are always explanatory.

La chirurgie de la douleur (3rd ed. Paris) Masson 1949 Pp 47 Fr 1450.—There is so much that is debated about the subject of pain and its causation and physiological basis that many interested investigators will welcome this new edition of Prof. René Leriche's book, which first appeared fourteen years ago. This author's unorthodox views on the causation of pain are based on his clinical observations extending over many years, and, though not all his deductions are acceptable to everybody, they have led him to devise methods of treatment which are often strikingly successful in alleviating pain. Operations on the sympathetic for this purpose are not generally accepted but readers of this book will feel that there is still much to learn as Professor Leriche freely admits. There are inexplicable failures. Even so the successes in the field of surgery, neglected because unexplored, are often more impressive than the failures. This book should stimulate efforts to elucidate the different problems of pain and the search for more reliable methods for its relief. Professor Leriche has an original approach to his subject, for which he has undeniably good grounds, based on observation. Others might with advantage follow his line of research.

failed to prove inherited susceptibility. Neither that matter has it been definitely shown that any peculiar environmental factor, such as poor diet, a damp house, or overcrowding, promotes susceptibility. FL WHITE, MAY WILSON, and others believe that a child is more likely to develop the disease if its parents or siblings are so affected, and for the purposes of prevention such children may be regarded as essentially susceptible. At the present moment, however, the only certain criterion of susceptibility is the history of a previous attack of rheumatic fever or chorea. There is as yet no test that can detect the rheumatic diathesis before the attack.

In the control and management of hæmolytic streptococcal infection there have been great advances. Washing of floors and bedding has been found to decrease airborne dust that may spread the organism in institutions such as fever hospitals. Adequate isolation of infected patients has resulted in a great decrease of cross infection, and much has been learned from the fundamental work of LANCEFIELD and GRIFFITHS, which showed that streptococci of many types which do not necessarily confer protection against one another. But perhaps most help of all has come from the new chemotherapeutic advances, for it is clear that chemoprophylaxis and chemotherapy can both play a part in reducing the incidence of rheumatic fever. With each of the two agents tried—sulphonamides and penicillin—there are no possible approaches to the problem: prophylactic treatment can be given over a long period to prevent the spread of hæmolytic streptococcal infections, or chemotherapy may be used in the established streptococcal infection to prevent rheumatic fever following gain. Both methods can be applied either to groups of susceptible subjects (such as the inmates of rheumatic fever hospitals) or to sections of the general population.

One of the first major contributions in this field was that of THOMAS and FRANCE,² who gave small amounts of sulphamylamide to rheumatic children daily during the winter months, and found that treated children had an insignificant number of relapses compared with untreated controls. This work has since been confirmed in Australia³ and the United States. There seemed to be few complications from sulphamide prophylaxis in rheumatic children, but attempts in the United States to extend mass sulphamide prophylaxis to military personnel at training centres, though promising at first, led to the appearance of sulphamide resistant strains of hæmolytic streptococci which made the method useless. Moreover, drug sensitivity developed in many cases, and is sometimes serious.⁴ Whether sulphonamides help to prevent rheumatism if used in the treatment of streptococcal sore throat is distinctly doubtful, though they will shorten the streptococcal illness, and evidence on the whole indicates that they will not modify the type or duration of the subsequent rheumatic fever.⁵

Oral penicillin offers an alternative to sulphonamides in the prophylaxis of rheumatic fever, though the dose has to take account of the fact that some four-fifths of the activity of penicillin is destroyed in the gastro intestinal tract. There is reason to think that the development of penicillin-resistant strains of organisms is not a serious difficulty here,⁶ and that both frank streptococcal infection and the symptomless carrier state can be prevented in rheumatic children.⁷ Though MASSELL and his associates⁸ at Boston also produced evidence that prompt penicillin treatment of streptococcal throat infections in rheumatic subjects will reduce the incidence of relapse, not everyone agrees that it does so, and cases have occurred in which the earliest possible penicillin treatment of a streptococcal throat infection has been followed by a severe rheumatic relapse. If, as most authorities now believe, rheumatic fever is the result of hypersensitivity of the connective tissues to something produced when the hæmolytic streptococcus infects the throat, the strength of the rheumatic reaction may bear no relation to the degree or duration of the streptococcal infection which initiates it—just as an explosion of gunpowder bears no relation to the size of the flame that lights the fuse. Hence in the treatment of a throat infection in a rheumatic person one would not necessarily expect penicillin to be valuable. A well designed study by DENNY et al.⁹ suggests, nevertheless, that it can prevent rheumatism from following streptococcal infection in people who have not previously manifested sensitivity. Treating upper respiratory infections in United States servicemen they gave crystalline procaine penicillin in oil with aluminium stearate, and gave it at the earliest possible moment—i.e., before the presence of the hæmolytic streptococcus was confirmed in the laboratory. Of 798 patients treated in this way, 2 developed rheumatic fever, compared with 17 of 804 controls who did not have penicillin. This finding obviously deserves close attention, but it should be borne in mind that the American workers may be dealing with acute rheumatic fever in a form rather different from the disease as we know it, since an incidence of rheumatic fever in 2% of untreated hæmolytic streptococcal throat infections is higher than would be expected among young men in this country.

In summary, therefore, it may be said that penicillin offers the possibility of preventing rheumatic fever. There are four ways of using it. Firstly, it may be given daily in prophylactic doses to rheumatic subjects to prevent streptococcal infection. Secondly, it may be given similarly to normal people living in groups where they are exposed to such infection.¹⁰ Thirdly, it may be given to rheumatic subjects as soon as they develop a throat infection. Fourthly, it may be given as a routine for all throat infections possibly attributable to a streptococcus. Of these four methods the first may be regarded as established and the last as promising, while the others are "not proven" and probably ineffective.

in a report¹ to the Medical Research Council. The studies in the two areas were conducted independently, and though they cover much common ground they are also complementary. In both areas, infection with the gravis type of *C. diphtheriae* had recently become prevalent and had led to an increased incidence of severe diphtheria which in Dundee was as frequent in the inoculated as in the uninoculated and showed also a higher attack rate than usual in the older age groups. In a preliminary study on Tyneside, examination of the blood serum from inoculated patients with diphtheria indicated that high levels of antitoxin might be found at the early stages of infection, and this paradoxical finding, only partially explained by faulty techniques in blood collection, led on to more exhaustive inquiries.

The assessment of antitoxic immunity was based on very careful estimations of the antitoxin values in the blood, and not on the Schick test which is more useful for measuring the over-all response to immunisation in a community than individual resistance to infection. Schick negative reactions have often been found in people with antitoxin levels from 0.01 down to 0.004 unit per ml and positive reactions in those with titres higher than the 0.03 unit at which SCHICK put the dividing line between resistance and susceptibility. Nowadays, a negative Schick reaction indicates an antitoxin level somewhere between 0.02 and 0.005 unit per ml, and it might be argued that this level is too low if the Schick test is to be used as an indicator of community resistance to diphtheria. It is obvious from the Tyneside and Dundee findings that an epidemic strain of *C. diphtheriae*—and this usually means a gravis strain—can overcome some degree of antitoxic immunity. What is less certain is whether a high antitoxic immunity, say of 0.5 unit or more per ml, will protect against clinical infection. It is true that 10–15% of the cases of clinical diphtheria among the inoculated in these two areas were found to have at least 0.5 unit per ml on their admission to hospital, but it is possible that these high levels resulted from the stimulus of the infection, which may have been present for some days before the clinical symptoms appeared. For example, in one small group of patients who were not given antiserum, the antitoxin content of the blood increased from 0.002–0.01 unit per ml on the second or third day of disease to 30–50 units per ml on the seventh to tenth day. Another significant finding was the different levels of antitoxin in three comparable groups of inoculated children in Dundee—children with diphtheria, children with other infections, and healthy children. About half of the first group had antitoxin titres of 0.004 unit or less per ml, compared with a tenth of the children in the other two groups, and at the other end of the scale only a tenth of the inoculated children with diphtheria but half of the other two groups had levels above 0.1 unit per ml. These figures indicate that during an epidemic children with low levels of antitoxin will be more susceptible to attack than those with higher levels. Nevertheless, it is not impossible for diphtheritic infection to occur in children with a high antitoxic immunity. Diphtheria in the inoculated is

almost always due to gravis or intermedius which are believed to have a much greater capacity than the mitis strain. It seems that such invasive strains could initiate a infection even though the toxin they produced quickly neutralised, just as a toxigenic strain of *Strep. pyogenes* may cause tonsillitis without a in people whose blood contains an effective level streptococcal antitoxin. The striking difference diphtheria in the inoculated and in the uninoculated lies in the severity of the infection, and this difference is to some extent correlated with the amount of circulating antitoxin. In the two areas studied, there were no deaths among the inoculated patients, though about a fifth of them had no circulating antitoxin on admission to hospital, which suggests that people with a basal immunity can mobilise antitoxin quickly enough to protect susceptible tissues from severe damage. The lesion often takes the form of a follicular tonsillitis without the typical adherent and confluent membranes and complications such as adenitis, myocarditis, and postdiphtheritic paralysis are much less common in the uninoculated.

In the campaign against diphtheria, our aim should be to eliminate clinical infection completely. This may be achieved by immunising 75% or more of the child population, which will reduce the total incidence of clinical infection and consequently the carrier rate and by maintaining the antitoxic immunity at as high a level as possible to protect the community against the more invasive strains. It is perhaps no coincidence that many of the severe outbreaks of diphtheria in the past twenty or thirty years have started in our ports—Bristol, Cork, Hull, Tyneside, and Dundee—and it may be that virulent variants of *C. diphtheriae* are introduced from time to time from abroad, for the prevalent strain in the Dundee and Tyneside outbreaks differed in some respect from the recognised indigenous gravis strains. The present diphtheria prophylactics, such as A.P.T. and P.T.A.P., give a Schick conversion rate approaching 100%, but we need more information on how to maintain a high level of antitoxic immunity over a long period. Meanwhile it seems wise to recommend primary immunisation in the first year of life, with further stimulating doses when the child enters and leaves school.

Prevention of Rheumatic Fever

RHEUMATIC fever is now generally regarded as a consequence of infection of the throat of a susceptible person by haemolytic streptococci of a Lancefield group. On this assumption we can try to prevent it in two ways: (1) by controlling haemolytic streptococcal infections, and (2) by detecting and protecting susceptible individuals.

Just what determines susceptibility is not yet known. Though many reports have shown that acute rheumatism tends to be familial, one has to remember that the children of a family usually have a common environment as well as a common inheritance, in particular they may share in exposure to haemolytic streptococcal infection. Extensive investigations, such as those conducted by the Medical Research Council in 1947,

acters among all human groups" In fact, given equal chances to develop their mental capacity, the average achievement of each ethnic group turns out to be about the same. And all groups have the one trait which has been at a premium in man's evolution—the power of learning by experience, adapting themselves to necessity. It is good to know that doctors have these things so much in mind that the British Medical Association has earnestly debated whether to forgo holding an annual meeting in a country with a colour bar, and that with African doctors have undertaken to do their utmost to prevent humiliation of coloured members at the association on that occasion. That such an undertaking should be necessary, and that it cannot be given the form of an assurance that no such humiliation will be attempted, is a grievous thing.

Unfortunately most people use the word "race" more loosely than the anthropologists. They apply it to national, religious, geographic, linguistic or cultural groups, and to each of these attribute fundamental differences of mind and nature. In fact, such groups do not necessarily coincide with racial groups at all, and their cultural traits "have no demonstrated genetic connection with racial traits." The authors of *The Europeans*¹ gave us the anthropological background for this conclusion: they showed from what a mongrel stock the caucasoid group has descended. The Jews, particularly, who have perhaps suffered more in the name of "race" than any other cultural group, prove to be as various in origin as the English. Peoples differ not in their nature or ability, but only in their social customs and history. "In our house we do it like this," says the child, and feels himself superior. Nations it seems, are much the same, and with as little cause for antipathy. Confucius, some 2500 years ago, summed it up: "Men's natures are alike, it is their habits that carry them far apart."

PROTECTION FOR LABORATORY ANIMALS

OUR Cruelty to Animals Act of 1876 ensures that animals used for scientific experiment in Great Britain are better protected than in any other country. In those days, admittedly, legislators were chiefly thinking in terms of surgical operations and were concerned to protect animals from the pain these might cause, whereas nowadays animals are used for many purposes, most of which cause no pain though they may entail discomfort. But it is doubtful how much would in practice be gained by re-writing an Act whose success depends so largely on good feeling. On the other hand, model legislation should at least be useful to humane people in other parts of the world where a programme of reform is badly needed. The Universities' Federation for Animal Welfare (UFAW) has therefore put forward a model Bill drafted by Major C. W. Hume, the secretary, which follows the existing law in many ways, but goes further in a number of directions. Like the Act it requires that those who experiment on animals should be licensed, and should work in a place registered for the purpose and subject to inspection, that operations should be done with the animal anaesthetised, and that no experiment should be done on an animal which occasions substantial suffering of more than moderate duration, or severe suffering of more than short duration, or extreme suffering, and that if an animal is found to be likely to suffer a degree more severe than any of these, it should be painlessly killed or fully anaesthetised, whether or not the object of the experiment has been attained. The Bill goes further, however, in covering not only laboratory animals, but animals used for the manufacture of sera and vaccines and the like, and it also protects unpopular

species—like rats—equally with popular species, like dogs, cats, and horses. The categories of pain outlined above are to be defined according to analogy and precedent, and examples are offered as a guide. Anaesthesia, too, is defined afresh, with particular attention to the degree of anaesthesia to be expected from electrical shock procedures. It is as well that this subject should be aired, for electric shock may leave an animal paralysed and apparently unconscious when it can in fact feel pain normally. Electrical shock methods are now used to kill animals in some slaughter houses, and there is evidence, as Major Hume has shown elsewhere, that they may even appear dead, when they are in fact conscious and suffering.

The Bill also proposes that the law should be administered by a Board of Control, appointed for the purpose from among humane scientists and veterinarians. This board would grant licences, appoint inspectors, and exercise discipline. Licences would be carefully graded according to the degree of suffering likely to be caused by the experiment, and would be issued only to scientists known to be technically competent and of humane temperament. A subordinate grade of licences would be issued to laboratory technicians, permitting them to carry out prescribed procedures under the experimenter to whom they were attached.

The draft of the Bill is now being circulated, and constructive criticism and comments will be welcome. Copies may be had from UFAW, 284, Regent's Park Road, Finchley, London, N 3.

PHARMACY OF P A S

THE increasing use of sodium p-aminosalicylate (sodium P A S), alone or with streptomycin and other drugs, in the treatment of tuberculosis has raised some problems for prescribers and dispensers. p-Aminosalicylic acid (P A S) proved too insoluble and unstable for convenience. The sodium salt, however, is readily soluble in water, and its aqueous solutions are reasonably stable, though they darken on storage, but for patients being treated at home it is probably wise not to order more than a week's supply at a time. Since 100 g of sodium P A S is equivalent to 72.5 g of P A S, prescriptions should indicate clearly which drug is being ordered. Sodium P A S at first tastes bitter and then intensely sweet, but Pugh and Jones, in their paper of July 15, noted that patients preferred taking it in a mixture, with syrup of orange and emulsion of chloroform as flavouring to swallowing a large number of tablets daily. It may also be prescribed in packets, each containing one dose, which the patient empties into a glass of water as required.

THE CONGRESS OF OPHTHALMOLOGY

THE sixteenth International Congress of Ophthalmology opened in London last Monday with an attendance of more than 1000 members from 64 countries. The Duke of Gloucester, who read a message of welcome from the King and Queen, presented the Gounon medal to Dr H. Arruga. The congress has not met in London since 1872, and its president is Sir Stewart Duke Elder.

THE sixth International Congress of Radiology will be held in London next week.

ON July 13 Sir CECIL WAKELEY was re-elected president of the Royal College of Surgeons of England. The vice-presidents for the year are Prof ERNEST FINCH (re-elected) and Mr P. H. MITCHNER.

Dr CHARLES HILL is resigning the secretaryship of the British Medical Association which he has held since March, 1944. At the last General Election he was returned as National Liberal and Conservative MP for Luton.

Annotations

BACK TO BASIC SCIENCE IN CANCER RESEARCH

A TREND that was conspicuous in last year's annual report of the British Empire Cancer Campaign has become still more evident in the work described for 1949¹. This has been towards the investigation of the properties of our experimental materials, whether cell constituents, carcinogenic chemicals, or physical agents, in terms familiar in the basic sciences. The pursuit of this trend must add to the difficulty of explaining the ways of the laboratory worker to the physician and surgeon, yet it is fully justified by the present state of cancer research and all experience of scientific endeavour.

The report provides plenty of examples of this type of investigation, the best illustration perhaps being the inquiries into the basic properties of nucleoproteins. These proteins have a twofold relevance to cancer—first, on account of their preponderance in nuclei and in intracellular synthesis, and second, because some of the nearest demonstrable continuing causes of a few special tumours, the virus tumours, are themselves particles of nucleoproteins. Much valuable work has been done, at the Chester Beatty Research Institute and elsewhere, on the chemical and physical properties of nucleic acids and nucleoproteins, including their interactions, either as isolated entities or within the cell, with various carcinogenic and related chemical and physical agents. From this institute also it has emerged that some of the carcinogenic aromatic nitrogen mustards induce numerical and structural alterations in chromosomes. And these alterations are self-perpetuating, though they are not necessarily an essential part of the malignant change. Other contributions to these studies come from the University of Durham, on the effects of radiation on nucleic acids (also on amino acids and sterols), and from Birmingham, where the investigations into fundamental chemistry and some of its practical applications have been continued. Attempts are being made to unravel the mechanisms of the two main reactions—the Dische and Feulgen tests—for the detection of ribonucleic acids in tissues. The synthesis of nucleoproteins is being studied with great ingenuity in the Department of Radiotherapeutics at Cambridge by the use of radioactive isotopes and X radiation. Apparently, it is now possible to detect interference in the synthesis of each of the two proteins separately when it is interfered with by X radiation. The extensive knowledge gained in this way and from the study of chemical enzyme poisons has led to a promising therapeutic procedure in this department. X radiation which can be localised is used in combination with enzyme-inhibiting chemical agents which act at a different stage in synthesis, so that the malignant cell is dealt a double blow. The survival times of patients treated with some of these combinations have encouraged further work on the same lines. Other centres engaged in nucleoprotein research are the Royal Institution (London) and Nottingham University.

Since the discovery of initiating and promoting factors in tumour induction—the first by a specific carcinogen, the second by a limited variety of "irritants"—more attention has been paid to the possibility that two or more factors may be operating in spontaneous carcinogenesis. At the University of Glasgow an enterprising attempt has been made to probe the causes of the high incidence of liver cancer among Asiatics and in the coloured races of Africa. It was thought that the cause might be in a combination of dietary deficiencies, which damage the liver and are common in Africa and the East, and a popular herbal remedy supplying the specific

carcinogenic factor. The herbal remedy suspected derived from *Senecio jacobaea*, which is known to cause liver damage in cattle. In experiments with this substance no tumours were obtained, but the idea is a valuable one. Working on similar lines, C. Hoch at the London Hospital was more successful. Liver damage was produced in rats by feeding them an inadequate diet containing a combination of amino acids in ardein (a protein derived from the groundnuts). Then 21 rats had chillies (cayenne peppers) added to this defective diet, and after seven months 12 of them had developed neoplastic changes in their livers. After twelve months no tumours had appeared in control rats on the same diet without chillies. The final outcome of these experiments should be instructive, and it will be interesting to hear what is found to be the responsible agent in the chillies.

The report mentions much other valuable work by clinicians, pathologists, and physicists that must remain unnoticed here. The volume should be studied in detail by all who are working in any field of cancer research.

HOMO SAPIENS

"... biological studies lend support to the ethical universal brotherhood, for man is born with drive toward coöperation, and unless these drives are satisfied, men and nations alike fall ill. In this sense, every man is his brother's keeper. For every man is a piece of the continent, a part of the main."

In this way a group of scientists drawn from various countries, with Prof. Ashley Montagu, of the United States, as rapporteur, sum up their findings on race problems. In a statement published on July 18 by the United Nations Educational, Scientific, and Cultural Organisation, they point out that all men belong to the species *Homo sapiens*, and that they most probably derive from a common stock. The drift and random fixation of the genes, the changes in their structure, and such factors as isolation, hybridisation, and natural selection are responsible for the differences between groups, as we see them, but the genes carrying such differences are few compared with the vast number which carry the likenesses. When set against the whole genetic constitution of man they are trifling, and show the hereditary differences between peoples to be no more than variations on a theme. From the biological standpoint, then, "a race" can be defined as one of the group of populations constituting the species. These populations are all capable of interbreeding, but geographical and other barriers which kept them apart in the past has produced in them some differences in physical characters which in the course of time may appear, fluctuate, or disappear. Races—or ethnic groups—are therefore few, the anthropologists are content to classify mankind into three main divisions—mongoloid, negroid, and caucasoid (which looks uncommonly like the yellow, black, and white of the nursery). Even these broad divisions fluctuate: they are not the same as they were in the past, and there is every reason to think they will change in the future. No biological harm comes of intermarriage between them, and statements that the children of such mixed matings show undesirable traits, such as "physical disharmony and mental degeneracies," are not supported by the facts. Race mixture of this kind has been going on from the beginning of man's time, and one of the chief processes of race formation and race absorption is through the crossing of ethnic groups. "The social results of a mixture whether for good or ill can be traced to social factors."

Nor is there any evidence that mental characteristics are among the items which differentiate ethnic groups. When allowance is made for differences of environmental intelligence tests show "an essential similarity in mental

¹ Twenty-seventh Annual Report of the British Empire Cancer Campaign for 1949. Edited by Sir Honenage Ogilvie. From 11 Grosvenor Crescent, Hyde Park Corner, London, S.W.1.

the approach of Harvey and his work, and that the tape which Harver adopted towards the facts, more maps than the actual physical discovery, was his real achievement. Sir Henry added "So clear are his observations and so cogent his reasoning that I would set that every medical student had *De Motu Cordis* as a set book for his preclinical study." I think that that is all the more necessary today, when we are a little apt to neglect the history of medicine, which is the basis of thought, and to confine ourselves to the achievement of medicine, which is the accumulation of knowledge. The counter attitude, the sudden reappearance of history as a criterion, a touchstone, is very difficult for us fully to appreciate. The best example of it, or one of the more striking examples, is in the presidential address by the President of the USSR Academy of Sciences, S. I. Vavilov, on the occasion of the 70th birthday of Stalin. He says there, "Soviet science is party science"—this is the herd of the Academy of Sciences speaking—it corresponds to the ideology of the vanguard of the advanced class, the working class, which is leading mankind to a better future."

"This Party character of our science determines in many ways its programme, its most important channels of development. The feature which sharply distinguishes our science in general is its clearly expressed materialistic foundation and practical direction. The struggle against idealistic tendencies in science which divert it from the correct course is characteristic of all fields of Soviet science. Unlike the situation in science in capitalist countries where idealistic tendencies have become particularly pronounced precisely in the last few years, Soviet science constitutes an impregnable materialist monolithic unit."

And he concludes "The days of so called pure science are gone forever in the Soviet country."

These are very uncompromising statements, and they are reinforced by a number of examples, some of which are very extreme. In the same address S. I. Vavilov said "The remarkable feature of the scientific theories of Lenin and Stalin is their infallibility"—an interesting appearance of that word. "One of the fundamental reasons of this infallibility lies in the impregnability of the foundation upon which Lenin-Stalin science is built. Its foundation is dialectical materialism." Infallibility! Well, it is easy to see that a very great stride is progress, away from the conception which we had sought previously to be almost axiomatic.

As I have said, this new attitude has been brought out clearly in the field of biology. In a way this is a great pity. Michurin's and Lysenko's contentions are well worth examination, as indeed any heretical doctrine is worth examination, for it is from the examination of heresy that true doctrine proceeds. The contention that Michurinism is scientifically untrue and Mendelism scientifically true is not the last word. That a good deal of further examination is necessary has been demonstrated by a great many keen and critical intellects in our own world. The keenest perhaps, and the most critical, is that of Bernard Shaw whose views against the whole argument of Weismannism are extremely interesting. In his recent review of *The Essential Samuel Butler* he held up Samuel Butler, another not inconsiderable intellect, to great praise because of his fierce denial of what he calls the Darwinian doctrine. He said "We picked up this stick, the doctrine of Natural Selection of Darwin and Wallace, which was carried to absurdity by Weismann. We all, Butler included, grabbed it and layed on joyously. Butler alone thought out deeply and quickly enough to grasp the horror of the banishment of mind from the universe"—which is a very interesting line. I note that neither Michurin nor Lysenko advocate their views as the establishment of mind in the universe, but rather as the establishment of

materialism, but by this time materialism has become in this context so conventional, so ritual a word that one takes it as one takes a coin abroad, hoping that it is of genuine mint, in circulation in the country concerned, but not necessarily current in other countries.

The stress which has been laid on the doctrine of Michurin, and afterwards of Lysenko, the denial of the whole machinery of genetics, the denial that the chromosomes have any place whatever in the inheritance of characteristics, the assertion of an absolute belief in the transmission of acquired characteristics—all these lead to the question whether this attitude is confined to the one field of science or whether it is part of a general denial of western scientific methods in all fields of science. The best comment so far, I think, has been given by Professor Eric Ashby, who is Harrison professor of botany in the University of Manchester. He brings down the question rather to the shortage of food in Soviet Russia and the necessity for any line which will lead to a short term advance in the productivity of the soil there. He says

The Achilles' heel of Soviet Russia is her food supply: therefore it is evident that the prestige of Lysenko must be preserved, whatever the cost. Unfortunately, owing to the bitter clash between Lysenko and the scientists over the aims and criteria of agricultural research, the cost has been very high.

"When the issue was fought in 1948 official support had to be given to Lysenko, but I do not think that any reputable Soviet scientist would regard this as more than a temporary expedient as more than a consequence of the anti-cosmopolitan policy of the Soviet Government and of the urgent need to improve agriculture."

"One distinguished Soviet scientist" Professor Ashby says "put it very well when he said at the discussion following Lysenko's paper that it is important 'at this juncture to cherish the prestige' of Lysenko."

Now, the question is, does this explanation cover the facts? There are certain facts which it does not cover. I give all weight to Ashby's views, I met him in the Soviet Union, he has himself lived there, he was director of the Scientific Liaison Bureau in 1942-43 and was the Counsellor of Australia in Moscow in 1945-46. His views in some ways are more objective even than the views of Julian Huxley, who gives evidence with a vehemence which in some ways is more theological than scientific. Ashby in his paper in the *British Medical Journal*, casts rather vigorous criticism on popular books on this subject, as for instance, *Russia Puts the Clock Back*, by J. Langdon Davies. He says "Mr. Langdon-Davies (unlike most geneticists) seems to regard Mendelism as sacrosanct, so that he feels obliged to defend it with the zeal of a medieval churchman defending orthodoxy." (You notice how religious terms begin to creep into the whole examination of this problem.) Ashby says "when he discusses biology Dr. Huxley is authoritative and scrupulously accurate, and when he discusses Russia he is much more modest and tentative than Mr. Langdon-Davies." Ashby says that the motive behind it all is still elusive. "No obvious interpretation arises from the facts as Dr. Huxley presents them." The Russians are very intelligent, says Ashby, among them are scientists as gifted as any in the western world. "Why, then," he asks "has the Russian Government attacked the very intellectual liberties which make scientific research possible? Why has it agreed to give public support to a fanatic whose scientific attainments would not qualify him for a junior post in a British University?" There he repeats the same argument which he uses in his reference to the Achilles' heel.

Russia's food supply is in the hands of a very simple, ignorant and lazy peasantry. When Lysenko comes among this peasantry with the zeal of a prophet and with such

THE TWO CONCEPTIONS OF SCIENCE*

WALTER ELLIOT

P.C., M.C., M.B., D.Sc. Glasg., F.R.C.P., F.R.S., M.P.

THE two conceptions of science are the absolute and the functional. The absolute considers science an end in itself, which does not admit question or justification, or, if there be any justification, the justification is simply the nature of man. The functional conception of science is that it is a handmaid to government, among many such, in which are included law, order, and armed force.

This clash is fundamental, and it is vital to our times. Its open emergence is healthy, as the emergence of any real clash is healthy—healthier, at least, than its suppression. But it is as well to remember that here is the shattering of the second great House of Faith which the Western world has built for itself, and, since mankind does not exist without some kind of shelter, the destruction of this House will be followed by the erection of another, which we cannot as yet discern.

Western civilisation's other name is Christendom. It had for its first shelter the House of Faith called Religion. It was a House of Faith so universally accepted that eventually to question it was reckoned as mortal sin—indeed almost as something pathological. Its authority was successively shaken by the Reformation, by the Encyclopædists, and finally by the failure to reconcile itself with the discoveries of science. Christendom, and the tenets of Christendom, are no longer the universally accepted conception of the Western world. This conception was gradually replaced by the conception of Progress or Perfectibility, which was a conception of the 18th century but persisted into the 19th, and was exemplified in such things as the simple belief stated by Victor Hugo that a single generation of universal education would completely transform mankind. Side by side with this went the conception of Knowledge, or, to use its ritual name, Science. It was thought that Nature was fundamentally good, fundamentally beneficent, and that the march of science, as it was called, would of itself bring not merely material but also moral advantages to those who joined in it. Even when doubts began to arise about the inevitability of Progress, the belief in Science, as a good to be pursued for its own sake, remained unchanging. This belief has now been sharply challenged by the Eastern world, or, to give it a geographical habitation, by the Soviet Union. The conception of science as an abstract ideal has been altogether denied.

The interesting fact is that this denial has evoked almost the same response as did the challenge to the other House of Faith, to the House of Religion, some hundreds of years ago. It is regarded almost as blasphemy.

One example with which we are all most familiar here is what is called the Lysenko controversy. But the same dispute has arisen in many other fields. Alexander Werth has described the same dispute as arising in the world of music. The conception of music as an art has been sharply denied and its position as a handmaid to government has been not only asserted but enforced. The existence of this conception in politics and in law is, of course, an older story.

The Lysenko controversy deserves attention because it is a working model, so to speak, of the whole clash. Furthermore, it has been set out in vigorous language by one very well qualified to speak, Dr Julian Huxley. He says

"It speedily became clear that the major issue at stake was not the truth or falsity of Lysenko's claims but overriding of science by ideological and political authority."

The Communist Party has officially pronounced Michurinism is scientifically true and Mendelism scientifically untrue. [Michurinism is the science of genetics enunciated by Michurin.] "It has divided science. Soviet science which is good and right, and the science which must be confuted by all Soviet scientists. Such a course of action in my view and that of the overwhelming majority of scientists is impermissible. To this is to destroy the necessary autonomy and unity of science as a major human action. This repudiation of the validity of science and scientific method is a denial of the freedom of the intellect which we fondly imagined has been laboriously won during the past three or four centuries."

FOUR BASES FOR BELIEF

Our Western attitude has been expressed a hundred times but never better, perhaps, than by Sir Henry Cohen in his recent Harveyian lecture on the Scientific Method. He is reported¹ as saying that

"There were four methods on which belief or doctrine might be based—namely, the methods of tenacity, of authority, of intuition, and of science or reflective inquiry. Tenacity, obstinacy, perseverance—call it what one pleases—was the basis of many medical doctrines commonly held to be true. A glance at medical textbooks made it plain that habit or inertia made it 'easier to continue to believe a proposition simply because we have always believed it.'"

We are all acquainted with that in practice. If an error does creep into a textbook, it has a singular way of reproducing itself in a number of other textbooks, and beliefs commonly held are maintained without any inquiry into whether the facts warrant it. I recently saw an instance of that myself.

I visited again, after a period of some years, the West Coast of Africa, the so-called White Man's Grave. Until quite recently it was considered to be inviting serious injury, if not death, to appear during daylight hours without a sun helmet. This was pushed so far that penalties were imposed on those who removed their sun helmets even for a very short time, and I believe the story is perfectly true, of a clergyman who was conducting a funeral service and, when one of the company at the graveside removed his helmet while the coffin was being lowered, said sharply "Put that on again. We don't want another one."

This practice has now entirely disappeared, indeed it is regarded, to use a vulgar phrase, as "cussy" to wear any hat at all. Though Africans go about covered, Europeans go about uncovered, and no ill effects seem to result.

It is therefore obvious that this belief, persisted in for so many years, so many decades, and so rigorously enforced, had no scientific foundation. It persisted, I think, until the appearance in large numbers, of the Royal Air Force who were not accustomed to take many things on trust, and insisted on going about without hats until they could find evidence to the contrary.

Sir Henry Cohen said that the second great method of belief was that of authority. This, I think, is the aspect which more particularly we have to examine as the one with which we are dealing in the Eastern world, because the third one, that of intuition, has not, I think, received any great support anywhere, since the collapse of Herr Hitler's vigorous experiment which was based largely upon this method. The fourth one is the method of science or reflective inquiry with which we are all very familiar.

AUTHORITY

As Sir Henry Cohen pointed out, the second form, the appeal to authority, was one which persisted in the Western world over a very long period of time. He was delivering this address on Harvey, and he said that "the purpose of discussion in Harvey's time was not to discover new facts but, in medicine, to demonstrate the truth of Galenic teaching." He pointed out how simple

* Presidential address to the Royal Institute of Public Health and Hygiene, delivered in London on June 29, 1950.

the approach of Harvey and his work, and that the attitude which Harvey adopted towards the facts, more than the actual physical discovery, was his real achievement. Sir Henry added "So clear are his observations and so cogent his reasoning that I would bet that every medical student had *De Motu Cordis* as a set book for his preclinical study." I think that that is all the more necessary today, when we are a little apt to neglect the history of medicine, which is the process of thought, and to confine ourselves to the achievement of medicine, which is the accumulation of knowledge. The counter attitude, the sudden reappearance of thorty as a criterion, a touchstone, is very difficult for us fully to appreciate. The best example of it, or one of the more striking examples, is in the presidential address by the President of the USSR Academy of Sciences, S. I. Vavilov, on the occasion of the 70th birthday of Stalin. He says there, "Soviet science is party science"—this is the head of the Academy of Sciences speaking—"it corresponds to the ideology of the vanguard of the advanced class, the working class, which is leading mankind to a better future."

"This Party character of our science determines in many cases its programme, its most important channels of development. The feature which sharply distinguishes our science in general is its clearly expressed materialistic foundation and practical direction. The struggle against idealistic tendencies in science which divert it from the correct course is characteristic of all fields of Soviet science. Unlike the situation in science in capitalist countries where idealistic tendencies have become particularly pronounced precisely in the last few years, Soviet science constitutes an impregnable materialist monolithic unity."

And he concludes "The days of so called pure science are gone forever in the Soviet country."

These are very uncompromising statements, and they are reinforced by a number of examples, some of which are very extreme. In the same address S. I. Vavilov said "The remarkable feature of the scientific theories of Lenin and Stalin is their infallibility"—an interesting reappearance of that word. "One of the fundamental reasons of this infallibility lies in the impregnability of the foundation upon which Lenin Stalin science is built. This foundation is dialectical materialism." Infallibility! Well, it is easy to see that a very great stride is in progress, away from the conception which we had thought previously to be almost axiomatic.

As I have said, this new attitude has been brought out chiefly in the field of biology. In a way, this is a great pity. Michurin's and Lysenko's contentions are well worth examination, as indeed any heretical doctrine is well worth examination, for it is from the examination of heresy that true doctrine proceeds. The contention that Michurinism is scientifically untrue and Mendelism scientifically true is not the last word. That a good deal of further examination is necessary has been demonstrated by a great many keen and critical intellects in our own world. The keenest perhaps, and the most critical, is that of Bernard Shaw, whose views against the whole argument of Weismannism are extremely interesting. In his recent review of *The Essential Samuel Butler* he held up Samuel Butler, another not inconsiderable intellect, to great praise because of his fierce denial of what he calls the Darwinian doctrine. He said "We picked up this stick, the doctrine of Natural Selection of Darwin and Wallace, which was carried to absurdity by Weismann. We all, Butler included, grabbed it and layed on joyously. Butler alone thought it out deeply and quickly enough to grasp the horror of its banishment of mind from the universe"—which is a very interesting line. I note that neither Michurin nor Lysenko advocate their views as the establishment of mind in the universe, but rather as the establishment of

materialism, but by this time materialism has become in this context so conventional, so ritual a word, that one takes it as one takes a coin abroad, hoping that it is of genuine mint, in circulation in the country concerned, but not necessarily current in other countries.

The stress which has been laid on the doctrine of Michurin, and afterwards of Lysenko, the denial of the whole machinery of genetics, the denial that the chromosomes have any place whatever in the inheritance of characteristics, the assertion of an absolute belief in the transmission of acquired characteristics—all these lead to the question whether this attitude is confined to the one field of science or whether it is part of a general denial of western scientific methods in all fields of science. The best comment so far, I think, has been given by Professor Eric Ashby, who is Harrison professor of botany in the University of Manchester. He brings down the question rather to the shortage of food in Soviet Russia and the necessity for any line which will lead to a short term advance in the productivity of the soil there. He says

"The Achilles' heel of Soviet Russia is her food supply, therefore it is evident that the prestige of Lysenko must be preserved, whatever the cost. Unfortunately, owing to the bitter clash between Lysenko and the scientists over the aims and criteria of agricultural research, the cost has been very high."

"When the issue was fought in 1948 official support had to be given to Lysenko, but I do not think that any reputable Soviet scientist would regard this as more than a temporary expedient, as more than a consequence of the anti cosmopolitan policy of the Soviet Government and of the urgent need to improve agriculture."

"One distinguished Soviet scientist," Professor Ashby says, "put it very well when he said, at the discussion following Lysenko's paper, that it is important 'at this juncture to cherish the prestige' of Lysenko."

Now, the question is, does this explanation cover the facts? There are certain facts which it does not cover. I give all weight to Ashby's views, I met him in the Soviet Union, he has himself lived there, he was director of the Scientific Liaison Bureau in 1942-43 and was the Counsellor of Australia in Moscow in 1945-46. His views in some ways are more objective even than the views of Julian Huxley, who gives evidence with a vehemence which in some ways is more theological than scientific. Ashby, in his paper in the *British Medical Journal*, casts rather vigorous criticism on popular books on this subject, as, for instance, *Russia Puts the Clock Back*, by J. Langdon Davies. He says "Mr. Langdon Davies (unlike most geneticists) seems to regard Mendelism as sacrosanct, so that he feels obliged to defend it with the zeal of a medieval churchman defending orthodoxy." (You notice how religious terms begin to creep into the whole examination of this problem.) Ashby says "when he discusses biology Dr. Huxley is authoritative and scrupulously accurate, and when he discusses Russia he is much more modest and tentative than Mr. Langdon Davies." Ashby says that the motive behind it all is still elusive. "No obvious interpretation arises from the facts as Dr. Huxley presents them." The Russians are very intelligent, says Ashby, among them are scientists as gifted as any in the western world. "Why, then," he asks, "has the Russian Government attacked the very intellectual liberties which make scientific research possible? Why has it agreed to give public support to a fanatic whose scientific attainments would not qualify him for a junior post in a British University?" There he repeats the same argument which he uses in his reference to the 'Achilles' heel'.

Russia's food supply 'is in the hands of a very simple, ignorant and lazy peasantry. When Lysenko comes among this peasantry with the zeal of a prophet, and with such

maxims as 'Keep down the weeds,' 'Space your millet more widely on dry soils,' 'Do not sow till soil temperatures are higher,' he does accomplish what in Russia are miracles—he brings production up to something like the level of that in western countries."

It is worth remembering, however, that these adulations of authority which I quoted earlier on are not confined to the sphere of biology alone. I have quoted already examples of the language used in biology. I quote one more. Here is an opinion on the work of Professor Glushchenko, doctor of biological sciences. The *Soviet News* says

"The work of Professor Glushchenko has not only practical but also great theoretical importance. Basing himself on Michurin's teachings and Academician Lyсенko's theoretical principles on the development of plants by stages, the author by concrete facts exposes the bourgeois Weismannites who deny the inheritance of acquired characteristics."

Now, you may say "Well, that only strengthens the point that this is attached to the development of food supplies and not to other aspects." But in astronomy, which is a long way removed from any immediate connection with food production, the Physico-Mathematical Section of the U.S.S.R. Academy of Sciences held a session at which reports were given on the latest research in astrophysics. The *Soviet News* states that "Soviet scientists have upset the theory of bourgeois, and especially American and Swedish, astronomers that the counter-radiance observed"—that is, in the "tail of the earth" outside the atmosphere—"is caused by an accumulation of meteorite-particles." It would seem therefore that the opposition to "bourgeois" scientists extends to certain phenomena in astrophysics.

I think one must take it that the extension of this unquestioning belief in the infallibility of authority is a feature common to all sections of Soviet science.† Here are greetings from the Central Committee of the Communist Party of the Soviet Union to Mr. Stalin when he was awarded the Order of Lenin.

"You have invested with your wisdom, indomitable energy and iron will each change, great and small, which raises our Motherland higher and higher. Great army leader and organiser of victory, you, Comrade Stalin, created the advanced Soviet military science. In the post-war conditions, guided by your directives, the entire Soviet people concentrated their creative initiative on the earliest liquidation of the aftermath of the war, on the realisation of the great plans for the further development of the national economy and culture of the country of Socialism, on the raising of the well being of the people. The Leninist-Stalinist ideas on Socialist emulation inspire Soviet patriots to new labour exploits, they have awakened great energy in the hearts of millions of Soviet people in the name of the great goal—the victory of Communism. With the greatest staunchness and insight, you, Comrade Stalin, direct the foreign policy of the Soviet Union. Great coryphaeus of science! Your classic works which develop Marxist-Leninist theory as applied to the new epoch, the epoch of imperialism and proletarian revolutions, the epoch of the victory of Socialism in our country, constitute the greatest possession of mankind, an encyclopædia of revolutionary Marxism."

These encomiums are not confined to any single set of achievements. I think it is clear that the hypothesis that

† Since this address was delivered, further confirmation of this view has appeared, in the recent official attacks on the leading Russian physiologists, who are accused of incorrect interpretation of the work of Pavlov. This line is of importance since Russia has been admitted by all as in the very forefront of physiology. One finds the party line now passed, that it is not so much the actual discoveries of Pavlov as their by-products (i.e., the materialistic interpretation of physiology) which are to be noted and followed up. The usual abject recantations by present senior scientists and teachers are now in progress. Future developments will be very significant here.

the Lyсенko controversy represents merely an cultural argument, in a limited field of scientific knowledge, does not fully meet the facts of the case, and I say, is having remarkable and immediate effects. Science is regarded as a handmaid to government, everything is regarded as a handmaid to the will of the governors.

EVIDENCE AND DOCTRINE

A very interesting example is referred to in the press. It has been advanced by the Soviet authorities for some time past.

There has been a considerable outbreak of the Colorado beetle pest on the Continent this summer. This has not been unknown in any part of Europe, there has been much evidence of it in the Channel Islands and elsewhere, it is something which is a feature of the present year. But it has been taken for granted now in Soviet circles that these outbreaks have been caused by the dropping of Colorado beetles from the air by American aeroplanes. This is now everywhere in the Soviet press stated as axiomatic and the Czechoslovak and other governments have formally accused the "Western Imperialists" of sending swarms of Colorado beetles into Czech territory to ruin the potato crop.

Thus in his report of June 15, 1950, Paul Merker, State secretary of the ministry of agriculture and forestry, Eastern Germany, stated that "over the whole territory of Saxony and Thuringia, over which American planes had flown 273,838 Colorado beetles had so far been found and in Mecklenburg 103,758. Many witnesses to the criminal activity of the Americans are cited in the report. On June 8, 1949, for instance, Heinrich Weber, a road inspector, near Mölhausen, noticed in the area of Road No. 247 a plane which was flying very low. The same aeroplane was also seen by railway inspectors Alfons Gross and Meinberg of Ahlbeck. Immediately after the passage of the aeroplane Colorado beetles were discovered, and following an organised search 9212 were caught. Labour Inspector Wilhelm Becker of Heimbürg-Schwerinburg reported that on June 10, 1950, he and many labourers working in the sugar beet fields of the National Estate of Heimbürg noticed trails behind an aeroplane flying at a great height from West to East. It later returned westwards. Immediately following the flight large numbers of Colorado beetles were detected on the sugar beet fields."

It is now regarded on this non-existent evidence as a scientifically proved contention that, whatever may be the case in other parts of Europe, the Colorado beetles in parts under Soviet control have been introduced by American aeroplanes. This is a very dangerous kind of acceptance of stated facts.

I think it is rather from the aspect of having facts stated by authority accepted without question that the challenge that one must examine the attitude of the Soviet authorities towards science. It is the general contention that authority must not be challenged or questioned. If you want to know the reason why, you will see it, perhaps, in the text of a broadcast address by Kim Ir Sen, chairman of the council of ministers of the Korean People's Democratic Republic, given on the radio on the morning of June 26 when he explained that hostilities had begun because Southern Korea had attacked Northern Korea.

"On June 25 the Army of the puppet Government of the traitor Syngman Rhee began an offensive on the territory North of the 38th Parallel. Courageously fighting, the Guards Detachments, which bore the impact of the enemy in stubborn battles, halted the offensive of the troops of the puppet Army of Syngman Rhee. The Government of the Korean People's Democratic Republic, having discussed the situation which had arisen, gave orders to our People's Army to go over to a resolute counter-offensive and to defeat the armed forces of the enemy."

Whereupon follows Kim Ir Sen's account of the operations to date. Clearly it would be a very unwise thing, a very undesirable thing, for anyone within its power

question the account that authority has given in statement

one might say, therefore, that it was clear that what are faced with was an iron assertion of authority—nothing else. But that is not entirely true. The riddle still remains an enigma. Only recently Stalin himself attacked, in the columns of *Pravda* the Sovietologist, N. Y. Marr, and said "One might think that before N. Y. Marr there was no such thing as linguistics. Marx and Engels were much more modest, and held that their dialectical materialism was a product of the development of the sciences, including philosophy, preceding periods." Edward Crankshaw points out that "two years ago the Soviet Minister for Propaganda, Alexandrov, was denounced and disgraced by Zhdanov for maintaining precisely this, instead of arguing that Marxism was a complete break with all the past." He thinks that in fact there are signs, not for the first time, at Stalin is less obscurantist than many of those who surround him. When he criticises the philologists he tries his warnings to a general contention. He says

"A régime has prevailed which is alien to science and men of science. The slightest criticism of the state of affairs in Soviet linguistics, even the most timid attempt to criticise the so-called 'new doctrine' in linguistics was persecuted and suppressed. Valuable linguistic workers and researchers were dismissed from their posts or demoted for being critical of N. Y. Marr's heritage or expressing the slightest disapproval of his teachings. Linguists were appointed to leading posts not on their merits but because of their unqualified acceptance of N. Y. Marr's theories."

It is interesting to speculate whether this is a manoeuvre or whether it is a departure. Time alone will show. At any rate, out of the mouth of the strongest, the most unquestioned of the Soviet authorities, Mr. Stalin himself, has come that statement. It is quite as strong as any statement by critics of the régime, and I think that some of our apologists for the régime will find it a little difficult to defend at once the actions and the criticisms which those actions have called forth.

THE PURPOSE OF THOUGHT

But the main conception in the world of the East is a conception from which the world of the West thought it had freed itself for ever—that is to say, that the purpose of thought is to serve government, and not to serve the general atmosphere in which alone the progress of mankind is possible, that in itself thought is not desirable, that thought is only desirable when it promotes the interest of government. That is a conception to which the Western world is opposed and to which scientific authority here, I trust, will offer the most uncompromising resistance. It is a clash, however, which I think is worthy of our closest attention both in theory and as we see, in immediate practical examples, since these are being brought, more and more vividly, with every 24 hours that pass, before our own personal attention.

DRUGS AND DRESSINGS IN HOSPITAL

ALL hospital doctors are being sent a copy of the letter on economy in the use of drugs, dressings, &c., which the chief medical officer of the Ministry of Health has already sent to general practitioners in the National Health Service.

Hospitals have been asked to draw the attention of all matrons and sisters to the rising costs of drugs and dressings, and particularly to the following recommendations:

(a) Economy in the use of dressings is the responsibility of the ward or departmental sister and such dressings should not be used for any unauthorised purposes. Suitable alternatives should be requisitioned and obtained.

(b) Matrons or assistant matrons should regard themselves as responsible for the periodic checking of ward require-

ments and assessing issues with the number and types of cases on that ward. The practice of wards having an excessive "spare" or "floating" stock should be discouraged.

(c) Expensive dressing should, for certain uses and when agreed by the medical officer concerned, be replaced by cheaper but equally suitable products—e.g., calico instead of lint as a base for ointment application in dermatological units and "hospital quality" cotton wool instead of B.P.C. quality.

(d) All abuse and waste of methylated spirits, ether, iodine, and other lotions should be avoided.

(e) The abuse of adhesive strapping for sticking notices, &c. should be avoided. Suitable alternatives should be requisitioned and obtained.

It is suggested that, "in order to facilitate the prescribing of standard, in preference to proprietary drugs," the hospital pharmacist should supply to each ward and consultative clinic a list showing the names of the common proprietary drugs in current use and of the *British Pharmacopæia* or *National Formulary* equivalents. He should also draw the attention of the hospital medical committee to any possible economies in the use of drugs and dressings, unless they can more appropriately be discussed with individual members of the medical staff.

Hospital authorities are asked to consider the periodic pricing of wards and departmental requisitions for dressings in order to draw attention to the high cost of these commodities. They "should arrange for the regular quarterly preparation, for their own consideration of a report by the finance officer, pharmacist and supplies officer to show the extent to which economies in quantities and cost are being effected."

Public Health

Food-poisoning in co. Durham

AN outbreak of salmonella infection involving 450–500 people in the village of Horden, co. Durham, has been traced to sandwiches, sausages, pies, pig's cheek, and pease-pudding made from a pig's carcass infected with *Salmonella newport*. The pig was slaughtered on July 1 because it had symptoms suggestive of intestinal obstruction but, apart from some enlargement of the liver and rather pale kidneys, no abnormality was found, and the carcass was passed for human consumption and delivered to a butcher on July 4. The pork, mostly ready cooked, was on sale on July 7 and 8, and symptoms of food-poisoning first appeared about midday on the 8th, the incubation period ranging from 18 to 96 hours. The illness usually lasted about five days. The organism has been isolated from the patients' stools and vomit, and from unsold portions of the pig's carcass.

Poliomyelitis

There was a sharp rise in notifications in the week ended July 8, the total being 212 compared with 160 in the previous week, but the increase was largely in non-paralytic cases, which rose from 36 to 73, while the paralytic cases rose from 124 to 139.

The principal increases were in Worcestershire, London, and Lancashire. The chief centre of high incidence is still in the Midlands though the figures for Warwickshire have declined a little.

Yellow-fever "Danger Zones"

The *Weekly Epidemiological Record* of the World Health Organisation for June 28 contains a new delineation of the two vast zones of prevalence of the yellow-fever virus in the tropical belts of America and Africa. The delineation which is a revision of that made by UNRRA in 1945–46 was finally accepted by all W.H.O. member States attending the third World Health Assembly last May. Further revision will take place as the situation warrants. In Africa plans are being made for a further study of the occurrence of yellow fever. In Brazil, favourable reports of the *Aedes aegypti* eradication programme with D.D.T. indicate that the mosquito will have been wiped out of the country before the end of the present year. It has already disappeared completely from all ports and cities and is found only in a small rural area in the north-eastern part.

BRITISH MEDICAL ASSOCIATION

THE annual gathering of the B.M.A. opened on July 13 at Southport. The representative body continued its discussions there until last Monday, and the meeting of the scientific sections began in Liverpool on Tuesday. The proceedings of some of the sections will be reviewed in our next issue.

In the course of his presidential address, delivered on Tuesday evening, Sir HENRY COHEN had this to say about undergraduate education¹

"Man is neither a pantechnicon nor a robot. His various organs and tissues, and his body and mind, are so closely

knit in maintaining or restoring health that our teaching must be pervaded by a 'synoptic' view. If basic medical training be directed to the study of the man, in relation to his external and internal conditions, it will be misconceived in aim, in structure, and in theory. Theory and practice must be closely integrated without theory practice lacks a guiding hand, and practice theory wilts. Students vary in their to learn and to be taught, they are as little suited to a uniform regimen of study as to uniformity of diet, or hobbies."

Representative Meeting

The annual representative meeting, over which Dr J. A. BROWN presided, brought to light a growing concern about the well being of the National Health Service and notably of the general practitioner service.

THE ACT AND AFTER

Dr REGINALD HALE WHITE (Marylebone) held that the "National Health Service is of course in a mess, and month by month it gets worse." This was not the fault of the profession, which had been allowed practically no say in the build up of it. The method of dictation by the Minister and subservience by the profession had been tried for two years. For the public the service was a wretched parody of what it might have been, and among doctors there was distrust and cynicism. Only by cooperation could a decent service be set up. At present it showed "signs of being the most costly and complete fiasco in our social history." The meeting agreed by a very large majority to the following Marylebone resolution.

"That this meeting affirms readiness to coöperate with the authorities in building up an efficient and smooth working National Health Service but deeply regrets that all efforts in this direction during the past three years have been frustrated by the cavalier treatment accorded to its representatives in their conversations and negotiations with the Minister."

Mr H. H. LANGSTON (Winchester) described doctors as "astrated, overworked, tired, and disillusioned. All were affected, but general practitioners more than others. All were unhappy and becoming cynical. The dissatisfaction was not purely financial, it was due to frustration above all else. The practitioner must have clinical freedom and access to diagnostic facilities, and he should not be snowed under with trivialities. Under existing conditions, what sort of man would enter practice ten to fifteen years from now? The association should publish a detailed plan for reform."

Dr R. KELSON FORD (Chelsea and Fulham) complained that in hospitals some consultants were being prevented from working by the limitations of the sessions system, and others were being turned out of jobs, registrars were having to enter general practice, for which they were ill equipped, hospitals often lacked necessary facilities, and bomb damage went unrepaired, and general practitioners had not had the Spens recommendations implemented. Rehabilitation of the National Health Service was an urgent necessity, but "I doubt if the nation can afford a really efficient service along the lines it is being run."

Dr A. V. RUSSELL (Wolverhampton) asked that thought should be given to (1) the curtailment of the widespread powers of the Minister, amounting now to dictatorship, (2) the free provision of drugs for private patients, and (3) the penal clauses.

Dr T. W. MORGAN (Kingston on Thames) contended that further needs of the practitioner were (1) that he

should obtain pathological and radiological reports direct, and (2) that he should have greater opportunities for admission to advisory and executive bodies. A tendency was to exclude the practitioner from everything—a policy which promoted frustration. Proposals for reform should be formulated not only by the Council but also by divisions and branches.

Dr J. C. ARTHUR (Gateshead), like Mr Langston, wanted a general review of the service, and a motion calling for a detailed programme of reform was carried.

A further motion called for the reconstitution of the Amending Acts Committee, to include, as well as ex-officio members, the chairman of the General Medical Services Committee, the Central Consultants and Specialists Committee, and the Public Health Committee, for members elected by the Representative Body, and for members elected by the Council. Dr H. ALEXANDER (Wandsworth) argued that one important function of this committee would be to scrutinise regulations tabled in the House of Commons. Dr E. A. GREGG, chairman of the Council, opposed the reconstitution of the committee. It would not, he said, be a policy forming body, and he would prefer that the motion was referred to the Council which would act on it when the time was opportune. The motion was nevertheless carried.

REMUNERATION

Dr S. WAND, chairman of the General Medical Services Committee, described negotiations with the Ministry of Health over remuneration. Practitioners, he recalled, had come into the service on the understanding that the Spens report would be the basis of remuneration. What was now being sought was not extra money but what should have been the remuneration from the appointed day. The Minister had been asked to indicate what he thought should be in the pool to implement the report. He, the Minister, had made it clear that he did not regard this report as necessarily a continuing factor, if the number of doctors doubled, he would not necessarily double the pool, because the work would then be halved. Dr Wand remarked that his committee, mindful of what had happened to the dentists, chemists, and ophthalmic opticians, had feared unilateral action by the Minister. The important thing at the moment was the betterment factor (or cost of living bonus). The association was claiming 70% betterment—though the correct figure was obviously nearer 100%. At present 40% was being given, and the difference between 40% and 70% was equivalent to about £7 million per annum.

On April 3 there had been a meeting with the Minister. He had conceded that if cuts were made at one point in the service, these might be balanced by an increase elsewhere. Dr Wand believed that the Ministry and the Minister himself were not unsympathetic to the practitioners' claim: the trouble was the Treasury. Health centres had been promised, and through not constructing

the Government had saved much money. Yet no extra was being offered to compensate the practitioner and his wife for the continuing difficulties of living from private surgeries. The Spens report had stated that not all of the ablest men should become specialists, but the best paid general practitioner was as well off as the lowest paid specialist. The status of the whole general practitioner group was lower than that of the specialist group—thus notwithstanding the increasing demand for a first class general practitioner service as the specialist service became more and more finely divided. Practitioners decided to withdraw, this would not mean they would stop giving services, it would mean only that the contracts with the Ministry would be terminated. With one dissenting representative, the Association reversed last month's resolution by the Conference of Regional Medical Committees,² which decided to prepare for withdrawal.

ARBITRATION

Dr CHARLES HILL, secretary of the association, described the present arbitration arrangements.

The Whitley machinery is voluntary and at present does not include provision for arbitration, an arbitration agreement being discussed. Section 13 of the Amending Act lays down that the Minister's consent is necessary before a case goes to arbitration. In certain circumstances the Minister of Labour may refer the case to a court of inquiry. Under the Conditions of Employment Order, 1940, the Minister of Labour must be notified of proposed withdrawal from the service, for then a dispute would exist. In the absence of voluntary machinery now the Minister of Labour might refer the dispute to compulsory arbitration and the association must then accept the result. If this Minister took no action within three weeks, doctors would be free to withdraw.

"I suggest," said Dr Hill, "that the Minister of Labour should probably choose compulsory arbitration." A motion calling for the immediate establishment of an independent court of arbitration, to settle disagreements on remuneration, was defeated. "Compulsory arbitration," Dr ARTHUR declared, "would be most generous to us." The Spens report was the arbitration and the report was given in the most favourable circumstances to practitioners. Others might hold that practitioners were not so badly paid. "What if a schoolmaster or a professor of Greek were on the tribunal?"

MEDICAL SERVICE COMMITTEES AND TRIBUNAL

Representatives agreed to ask the council to investigate the composition and procedure of the tribunal and medical service committees. Dr R. FORBES (Hendon) said that changes were needed, to protect the practitioner. Dr J. A. GORSKY (Westminster) observed that the tribunal did not publish its proceedings but only its conclusions, it acted, not judicially, but on a basis of expediency and policy. This issue did not affect doctors and Lord Samuel was seeking a remedy in a Bill which he had introduced into the House of Lords.

CHANGE OF DOCTOR

Following representation by the General Medical Services Committee, the Ministry of Health has proposed that a patient who wishes to transfer to another doctor should have to give a fortnight's notice. After a lively discussion representatives agreed that they favoured the proposed procedure. Dr C. W. WALKER (Cambridge) reasoned that change of doctors should not only be free but should seem to be free. Doctors disliked treating a patient who would prefer to be under someone else but did not have the courage to change, and this new procedure would increase the numbers of such people. Dr D. L. LICK (East Herts) argued that the relationship between doctor and patient was one of confidence, and

once confidence was broken, it was better not to try to continue the association. Dr A. M. MAIDEN (Lincoln) expressed an opposite view. There was a growing drift of patients towards doctors who gave way to their requests, in the interests of everyone—and of economy—this drift should be checked, and the new arrangement would act as a check. Dr DORIS ODUM (Bournemouth) held that the liberty, hitherto existing, to change doctors freely, encouraged the belief that doctors were people of no importance. Dr E. A. GREGG, chairman of the council, maintained that the unhappy patient should be enabled to escape at once rather than be made to stay—in which event he might cause trouble. "I am for free choice at any moment." Dr J. A. PRIDHAM (Dorset) said that doctors were always protesting that they wanted freedom. Yet now, when it suited them, they wanted a new regulation. Furthermore, the proposed obstruction to free change favoured the older man who already had a large list. Dr WAND fancied that those who spoke against the change were all rural practitioners. The towns had floating populations, and since 1948 the number of changes had increased several fold. The amended procedure, which was a compromise between two extremes, would have a salutary effect.

UNJUSTIFIED CALLS

The meeting concurred with a Hendon resolution that the regulations should be amended to provide the practitioner with the right to lodge a complaint against a patient who made frivolous or vexatious demands. It agreed, too, that the patient should be penalised where his demands were proved unreasonable, but representatives were unable to suggest a suitable penalty.

REPRESENTATION ON BOARDS AND COMMITTEES

Representatives expressed unanimous concern over recent action taken by regional hospital boards to exclude general practitioners and other doctors from membership of hospital management committees. Dr W. N. LEAK (Mid Cheshire) cited an instance where a regional board had refused to reappoint a candidate who seemed very suitable to the executive council. Dr T. ROWLAND HILL (Marylebone), while sympathetic to the general practitioners' claims, insisted that consultants and practitioners must face this issue together, for if the two branches did not unite their disunity would be exploited, already consultant membership was falling. Dr F. M. ROSE (Preston) held that each board and management committee should include one general practitioner. Dr FRANK GRAY (council) said that the three sections of the service were tending to develop separately, representation of practitioners would go some way towards counteracting this trend, and they were seeking it not as a privilege but as a duty. Dr H. N. GREGG (Coventry) said that in his area other professional employees were being forced off the committee, general practitioners would go next, and then the consultants. The danger of successful political nominations had to be guarded against, and all groups of doctors must stand or fall together.

Dr WAND said that the Ministry had promised early clarification of the offending circular (issued last November) under whose terms the regional board had dealt with the case described by Dr Leak.

Representatives went on to vote in favour of adequate representation, through election or nomination by the profession, of consultants, general practitioners, and, where applicable, medical officers of health, on boards and management committees, and they expressed disquiet at the insufficient and diminishing representation.

Dr C. METCALFE BROWN (council) spoke of the contribution that medical officers of health could make to hospital management. They were, he pointed out, concerned with infectious diseases, mental deficiency, the maternity services, and tuberculosis.

² See *Lancet* July 8, 1950, p. 61

ADVISORY COMMITTEES

The meeting voted in favour of approaching hospital medical advisory committees with a view to securing general practitioner representation on them.

Mrs G M SANDS said that here and there group medical advisory committees were being set up under the aegis of the management committee, and the authority of advisory committees of individual hospitals was being curtailed. She saw in this a drive towards placing the hospitals and their staffs under lay administrative control.

GROUP PRACTICE

On a motion that the Minister should provide suitable health centres and press local authorities to provide accommodation for group practice, Dr G O BARBER (Mid Essex) said that much had been heard about the degradation of the general practitioner, but less about attempts that practitioners were themselves making to meet present day needs. Here and there groups had come by existing premises and altered them to provide a centre for group practice, including ancillary help and duty rosters. There were also a good number who would like to do this but were afraid of the initial capital outlay. In Dr Barber's view, the whole future of general practice depended on doctors being able to work under good conditions, with ancillary help and with enough time off—benefits that group practice could provide.

Dr F A GREGG reported that in London people were pressing for health centres in all sorts of unsuitable buildings. The association's policy was to proceed with experimentation. It would be a pity if, through pressure on local authorities, a number of pseudo health centres were set up to help group practice, and if these were afterwards dubbed health centres. This issue should, he thought, be referred to the council. The resolution was, however, adopted.

DIAGNOSTIC FACILITIES

Dr ROSE secured unanimous support for a resolution reiterating the Representative Body's claim that X-ray and laboratory diagnostic resources should be available direct to practitioners. The delay suffered by the patient in waiting for an outpatient appointment was farcical. Commonly, practitioners were having their work filtered by young doctors who had been qualified only six months. It had been claimed that the diagnostic departments could not stand the extra strain of receiving work direct from practitioners, but in one instance where this course had been adopted the work for the outside doctors accounted for only some 20% of the total in the X-ray department and some 8% in the pathology department. This arrangement was vital to the practitioner if he was to retain a high standard. It was in the interest of consultants that practitioners should be interested in medicine and should be able to offer a reasonable diagnosis.

Dr FERAGCON ROBERTS (Cambridge) repeated the assertion he made last year—that direct reference by the practitioner does not mean more work, and that the outpatient department is no filter. In fact, he said, the medical outpatient department asks for a great deal more than does the practitioner. Two of the arguments advanced against giving direct access were (1) that no history would accompany the patient, and (2) that the general practitioner would be incompetent to apply the appropriate treatment. These arguments he could not accept. In his X-ray department he could easily accept cases from general practitioners, but the hospital had refused permission.

A further motion was carried calling for the establishment, as a temporary measure, of centres to provide the general practitioner with ancillary aids where these were not available. Dr T F TIERNEY (Marylebone) objected that the radiologists to staff these centres were

not to be had, and W SMITH (Greenwich), as a logist, alleged that at the present time the radiology pathology were not sufficient even for the needs of themselves. Dr D M HUGHES (South West) spoke of the indispensable help given to him by the Public Health Laboratory Service in suppressing an outbreak of scarlet fever among school children.

TRAINEE SPECIALISTS

Mr WELDON WATTS (Newcastle upon Tyne) spoke to the uncertain future of registrars. Only a short time ago, he said, these totalled 5000, and the likelihood of consultant vacancies each year was 200. Mr S MAYNE (Plymouth) emphasised the difficulty experienced by the registrar from the non-teaching hospital in getting a consultant post. Mr NEWELL announced that the Central Consultants and Specialists Committee suggested that in each region a committee should be set up to see that the number of registrar appointments kept within bounds, and to promote interchange of registrars between teaching and non-teaching hospitals.

The meeting adopted a Perth resolution requiring that the trainee specialist should spend at least a year in general practice, in order (a) to fit him to train other general practitioners, and (b) to give him a wider outlook. It was pointed out that at present the specialist training tends to engage at all in general practice, because he might be passed over, and secondly because he believes that any contact with general practice does him only harm. An advantage of this year in practice would be that young doctors might find that the hospital had attractions and decide to pursue it.

GENERAL PRACTITIONER AND HOSPITAL

Mr A STAVELEY GOUGH, chairman of the committee on general practitioner and hospital work, succeeded with a resolution in the following terms:

- 1 That the smaller general practitioner and cottage hospital should be retained by the general practitioner, and that certain wards in district hospitals should be set aside for the treatment of patients by general practitioners.
- 2 That, for educational purposes, clinical assistantships should be set up, (a) allowing for periods of approximately two years at least in any particular specialty, and (b) allowing for short periods in two or three specialist departments.
- 3 That part-time appointments should be established held by general practitioners.
- 4 That in rural areas the appointment of part-time general practitioner specialists should be retained and encouraged. Such appointments will both benefit the Service and assist practitioners who, having had specialist training, are reluctant or unable to obtain consultant appointments. General practice in these localities should be no bar to the holding of a specialist appointment.
- 5 That the attendance of general practitioners at hospital rounds, clinical and scientific meetings and inclusion in the hospital team.

Dr A C R GETHEN (Guildford) reported that in his area a team of practitioners had for some time worked as clinical assistants in a local hospital. Despite the Minister's directive encouraging this arrangement, the whole team had last month received notice of the termination of their contracts.

OTHER BUSINESS

After protracted discussion in committee it was decided to accept the invitation of the South African Medical Association to hold next year's meeting at Johannesburg, jointly with the South African Medical Association. Dr A W S SICHEL (Cape Town) was elected president for 1951-52.

Representatives adjourned shortly after noon on Monday, having dealt with only about two thirds of the items on the agenda. The remainder will be considered at a meeting in London this autumn.

unning Commentary by Peripatetic Correspondents

INTERESTING query is there a larger sale for books of the nature of the bacterial surface or for books of al exegesis? I don't think anyone—not even a uttee of the Royal Society—really knows how to 'what matters' readily available to those who d learn I am supposed to be a bacteriologist, but ow nothing at all of bacterial chemistry and little gh about the theoretical aspects of immunity I to the hope that from time to time the great hesiser arises—who combines basic education, wide ing, and a mind both lofty and leisurely—and folds he detailed learning of the years past, puts it away ie bottom drawer and leaves us with a few unassail- propositions on which to base our future guesses h as chaps like Bacon turned all the wisdom of the lle Ages from an intellectual cat's cradle into rather ous archaeology

okers can roughly be divided into (1) those to whom king is just one of their several pastimes and those to whom it is part of life itself. The first gory, whatever their reason for taking to smoking, did not smoke at all and anyway they don't need extraneous aids if they want to give it up. Some he second category, perhaps because they are told are slaves to a habit," or because it's too expensive because their wives object, or because they can't their favourite brand of cigarette or tobacco, or for e other reason, will sooner or later try to give it up t stopping is impossible and they'll try some aid. per sulphate is said to make cigarettes distasteful. ven t tried it, but a dilute solution of silver nitrate is as good. After using this as a mouth-wash I found t a cigarette tasted so terrible that after a few mpts I poured the mouth-wash down the drain and akfully enjoyed my evening smoke cancer or no cer of the lung

We went into the surgeon's room for welcome coffee during the morning's list. I waited respectfully for his choice in conversation. He mentioned some details of the last case—a simple mastectomy—and added, "I've never been convinced of the lack of bias among those who advocate breast-feeding rather than artificial. I fail to see why, even if now the former is just the better science should not advance a few steps and soon eliminate the inequality. The human mamma would then be redundant, apart from its erotic aspect. I've always considered its conventional clothed contour an example of feminine dishonesty: the outline natural only in adolescence and late pregnancy is mutated throughout adult life by the coercive influences of bands and straps. It is questionable whether a completely artificial breast is not a more honest compromise with present accepted standards."

He paused and sipped coffee before going on reflectively. "I wonder what will happen if there is a third world war. In the first one women deigned to soil their fingers in field and factory. In the second they were asked to donate their private culinary possessions, while he fit ones were compelled to perform duties of national importance, often joining the fighting forces. It is fair to assume that next time the odds will be more finely balanced before the fight begins. Women, along with the rest of us, will be asked to make even greater sacrifices, possibly more personal ones, and the flat chest may be as envied as the much be-ribboned one."

"You foresee a return to the Amazon era, then?" I asked. "Not so," he replied. "That appellation was etymologically incorrect. The fabulous women concerned are said to have had their right breasts removed because interference with the incursive twang of the bowstring resulted in local pain, distant inaccuracy, or both. The term Amazon implies that they had no breasts, Monomast or Monomazon would have been more correct. On the contrary, therefore, the age of the true Amazon is yet to come."

He drained his cup and rose. There was a smile on his face as we returned to the theatre. I think it had occurred to him that he would be dead and gone long before that.

I read out loud from the newspaper that the German Chancellor Herr Adenauer, was ill. "Gott sei Dank!" exclaimed our German domestic help. "What did you say?" I asked, startled. "Gott sei Dank," she repeated. "Don't you like him?" I asked. "I don't mind him," she said coolly, "but in Germany we always say 'Gott sei Dank' when anyone at the top is ill, we are glad to know that they, too, can be ill like us poor people."

Schadenfreude is an expressive German word without an English equivalent and if such a primitive and childish emotion as malicious pleasure in the misfortune of another is generally regarded as typically German this is largely because harshness from those in authority brings its reaction from those below. The toad must hate the harrow and rejoice to see it rusty or broken. The Bonn government is no doubt mild and progressive but for a long time to come the rulers of Germany will be reaping the harvest sown by their predecessors.

Peter, aged 6, often keeps me company on my rounds. The other day we went to try and catch a glimpse of the tonsils of a nervous little boy whose father is a sculptor. Fortunately his mother was out, so we let ourselves in quietly by the back door and completed the examination without difficulty. Then we went down to the studio at the bottom of the garden to report to father. We had never been inside before and Peter was enthralled by the carvings. As one might have expected he made a bee-line for a large study of a female nude standing in the corner and gazed at it in rapt astonishment. It has been necessary in the past to curb his own artistic proclivities in a certain direction, so perhaps I should have felt encouraged when he turned to the embarrassed young sculptor and asked in a reproachful tone "Did you do that?"

The tension relaxed as I stepped out of the plane and almost straight into the waiting airport bus. An air-hostess took the seat in front of mine. She clearly was not one of ours, but I could not place her cap-badge. Her profile as she asked me for a light was international—a face to launch a thousand of these new ships of the clouds. Her hair was windswept, superficially a glistening gold its deeper layers a less lustrous but no less attractive bronze. The traffic lights were against us, and the bus pulled up with a jerk. The gold parted in a new place. There, clinging firmly to a duller strand, was a small pearl-grey object. The lights went green. The bus started again. The pearl was hidden from view. At each traffic light I followed its progress upwards to its goal beneath that cap. A minor infestation? Perhaps, but an infestation all right. All that glistens is not gold.

Quite the nicest living creatures at the fête were a couple of field-mice who spent the afternoon feeding and running round the boots and shoes of the assembled company. The next nicest thing was a half-grown scraggy chicken which was walking about unconcernedly picking up unconsidered trifles within easy reach of the jaws of the dogs waiting to compete in the comic dog show and expressing resentment at being tied up. The third nicest things were the dogs themselves. With certain exceptions the human beings were the least nice.

A million silly questions
Come every day unsought.
By phone, by post, in surgery,
Or on the road from A to B
Always pursued by somebody,
I'm catechised when caught
A million silly questions
(Guessed-to the nearest nought)
I wonder if—as well I may—
I give, in my abstracted way,
A million silly answers, eh?
H'm. Formidable thought.

ADVISORY COMMITTEES

The meeting voted in favour of approaching hospital medical advisory committees with a view to securing general practitioner representation on them.

Miss G. M. SANDES said that here and there group medical advisory committees were being set up under the aegis of the management committee, and the authority of advisory committees of individual hospitals was being curtailed. She saw in this a drive towards placing the hospitals and their staffs under lay administrative control.

GROUP PRACTICE

On a motion that the Minister should provide suitable health centres and press local authorities to provide accommodation for group practice, Dr G. O. BARBER (Mid Essex) said that much had been heard about the degradation of the general practitioner, but less about attempts that practitioners were themselves making to meet present day needs. Here and there groups had come by existing premises and altered them to provide a centre for group practice, including ancillary help and duty rosters. There were also a good number who would like to do this but were afraid of the initial capital outlay. In Dr Barber's view, the whole future of general practice depended on doctors being able to work under good conditions, with ancillary help and with enough time off—benefits that group practice could provide.

Dr E. A. GREGG reported that in London people were pressing for health centres in all sorts of unsuitable buildings. The association's policy was to proceed with experimentation. It would be a pity if, through pressure on local authorities, a number of pseudo health centres were set up to help group practice, and if these were afterwards dubbed health centres. This issue should, he thought, be referred to the council. The resolution was, however, adopted.

DIAGNOSTIC FACILITIES

Dr ROSE secured unanimous support for a resolution reiterating the Representative Body's claim that X-ray and laboratory diagnostic resources should be available direct to practitioners. The delay suffered by the patient in waiting for an outpatient appointment was farcical. Commonly, practitioners were having their work filtered by young doctors who had been qualified only six months. It had been claimed that the diagnostic departments could not stand the extra strain of accepting work direct from practitioners, but in one instance where this course had been adopted the work for the outside doctors accounted for only some 20% of the total in the X-ray department and some 8% in the pathology department. This arrangement was vital to the practitioner if he was to retain a high standard. It was in the interest of consultants that practitioners should be interested in medicine and should be able to offer a reasonable diagnosis.

Dr FFRANGCON ROBERTS (Cambridge) repeated the assertion he made last year—that direct reference by the practitioner does not mean more work, and that the outpatient department is no filter. In fact, he said, the medical outpatient department asks for a great deal more than does the practitioner. Two of the arguments advanced against giving direct access were (1) that no history would accompany the patient, and (2) that the general practitioner would be incompetent to apply the appropriate treatment. These arguments he could not accept. In his X-ray department he could easily accept cases from general practitioners, but the hospital had refused permission.

A further motion was carried calling for the establishment, as a temporary measure, of centres to provide the general practitioner with ancillary aids where these were not available. Dr T. F. TIERNEY (Marylebone) objected that the radiologists to staff these centres were

not to be had, and W. SMITH (Greenwich), a radiologist, alleged that at the present time the radiology pathology were not sufficient even for the needs themselves. Dr D. M. HUGHES (South West) spoke of the indispensable help given to him by the Public Health Laboratory Service in suppressing an outbreak of scarlet fever among school children.

TRAINEE SPECIALISTS

Mr WELDON WATTS (Newcastle upon Tyne) spoke of the uncertain future of registrars. Only a short time ago, he said, these totalled 5000, and the likelihood of consultant vacancies each year was 200. Mr SIR MAYNE (Plymouth) emphasised the difficulty expected by the registrar from the non-teaching hospital in getting a consultant post. Mr NEWELL announced that the Central Consultants and Specialists Committee suggested that in each region a committee should be set up to see that the number of registrar appointments kept within bounds, and to promote interchange of registrars between teaching and non-teaching hospitals.

The meeting adopted a Perth resolution requiring the trainee specialist should spend at least a year in general practice, in order (a) to fit him to train for general practitioners, and (b) to give him a wider outlook. It was pointed out that at present the specialist training fears to engage at all in general practice because he might be passed over, and secondly because he believes that any contact with general practice would do him only harm. An advantage of this year in practice would be that young doctors might find that the hospital had attractions and decide to pursue it.

GENERAL PRACTITIONER AND HOSPITAL

Mr A. STAVELLEY GOUGH, chairman of the committee on general practitioner and hospital work, succeeded with a resolution in the following terms:

- 1 That the smaller general practitioner and cottage hospital should be retained by the general practitioner, and that certain wards in district hospitals should be set aside for the treatment of patients by general practitioners.
 - 2 That, for educational purposes, clinical assistantships should be set up, (a) allowing for periods of approximately two years at least in any particular specialty, and (b) allowing for short periods in two or three specialist departments.
 - 3 That part-time appointments should be established and held by general practitioners.
 - 4 That in rural areas the appointment of part-time general practitioner specialists should be retained and encouraged.
- Such appointments will both benefit the Service and attract practitioners who, having had specialist training, are reluctant or unable to obtain consultant appointments. General practice in these localities should be no bar to the holding of a specialist appointment.
- 5 That the attendance of general practitioners at hospital rounds, clinical and scientific meetings, and inclusion in the hospital team.

Dr A. C. R. GETHEN (Guildford) reported that in his area a team of practitioners had for some time worked with clinical assistants in a local hospital. Despite the Minister's directive encouraging this arrangement, the whole team had last month received notice of the termination of their contracts.

Letters to the Editor

THE INFECTIOUS TUBERCULOUS

SIR,—It is a great pity that any mention of infection in tuberculosis is apt to arouse most unreasonable emotions, even in those who should know better. No such fault can be found with the eminently sensible letter from Dr Greuville Mathers and Dr Trenchard (July 8), but your annotation in the same issue showed regrettable signs of "tuberculophobia." Witness the remark that some positive sputum patients are "actually discharged from sanatoria in this dangerous state." Or again, "in their sanatoria they were taught that they were a danger to others." In fairness to the tuberculous, recognised authorities ought not to make such sweeping accusations, which may lead to unjust ostracism, without first examining the facts.

There is no proof that the patient with *known* tuberculosis is an important factor in the spread of the disease, in fact, all the evidence seems to point the other way. It is well known that in tuberculosis colonies the incidence of clinical disease among the children is extremely small, and those who examine child contacts confirm that it is rare for a child to contract tuberculosis when in contact with a patient who knows that he has the disease. Again, the statements of patients who are supposed to have been infected by known contact almost always show an association with some person who *subsequently* was found to have tuberculosis, not with a diagnosed case. All this suggests that tuberculosis is a disease of relatively low infectivity and therefore simple to control, and that the educational level of our population is just sufficiently high to ensure that the majority of persons who know that they have the disease will take enough care to prevent it from spreading. They should be taught in the sanatorium, not that they are a danger to others, but that they need not be dangerous if they obey certain rules—the difference is important. As you so rightly point out, they must be given the opportunity to be careful and they must not be forced into close contact with their fellows, but control of tuberculosis will never be achieved by concentrating our fears upon these treated patients who are comparatively harmless.

The real menace is the unknown carrier. Much more could be done by better case finding (which means more beds) and by teaching everybody to take simple precautions against the spread of respiratory infections. It is a pity that the Ministry of Health no longer publish posters about "coughs and sneezes spread diseases" and more imaginative propaganda is necessary to stir up public opinion against those with careless habits. It is probable that if the teaching and enforcement of "handkerchief hygiene" were made compulsory in all schools, it would drastically reduce both the incidence of tuberculosis and also the man hours lost to industry by other respiratory infections. Such simple measures are likely to be far more effective than expensive schemes for segregating the tuberculous or promoting research into the nature of the common cold.

Brompton Hospital Sanatorium A F FOSTER CARTER
Frimley, Hants

CLINICAL PATHOLOGY

SIR,—Can nothing be done about this "sausage machine" pathology? My old chief, Prof E H Kettle, once said to me that a hospital needs a clinical pathologist in the same way as it needs a chaplain, and I believe that saying contains a profound truth. I picture the patient whose "en de cœur" is passed on through a series of probationer nurses, hospital porters, and technicians, the final message of spiritual comfort being typed by a clerk with the chaplain's signature appended.

This is what is happening in clinical pathology. Admittedly, senior technicians are highly skilled, they are relatively rare, and even they are no pathologists than ward sisters are doctors. It is usually not they but quite junior people who see the patients. The result is that the doctor knows nothing of the patient being investigated cannot check the errors, conscious or unconscious, clerical or technical, which can and do occur.

I am sure that the pathologist's duty is to take part in investigations, both at the bedside and at bench.

New Sussex Hospital,
Brighton

M A LESLIE SMITH

COMPULSORY HOUSE-APPOINTMENTS

SIR,—The Goodenough Committee made the sensible suggestion that men and women qualifying in medicine should spend twelve months in house appointments before registration. This was already the practice of the better students. The medical student is dazed by study when he qualifies and needs a year to find his feet. He must learn to take responsibility within the shelter of an institution before he can take it outside. The proposal was generally welcomed and nothing would have appeared simpler than to put it into effect. All that is necessary is to designate certain posts as A1 and A2 and to decide that no man will be registered till he has held two such posts. The graduate should still be assumed to have the requisite knowledge and skill for the practice of his profession, and should be given the proper opportunity and remuneration for practising within the hospital system.

Assuming, as we must, that most of the Scottish and Irish graduates will have to find appointments in England and Wales, the total number required will be 2500 to 3000 a year. The Supplement to the *British Medical Journal* of July 27, 1940, gave the total of junior hospital posts as 4143, and similar figures have been quoted in recent discussions on the National Health Service. Some subjects, however, are inherently unsuitable for the newly qualified man, and among these I should put mental diseases, and a good deal of geriatrics and chronic sickness. It may well prove that more than half the hospital accommodation in the country is unsuitable for first year graduates.

The teaching hospitals have 26,000 beds. Not all these will be suitable for the first year graduate, and even assuming that one man looks after only 20 beds there are unlikely to be 1000 suitable house appointments in the teaching hospitals. Our Oxford Regional Board has 13,500 beds of which about 2000 are for general medicine, general surgery, obstetrics, gynaecology, and paediatrics. This would imply 40,000 suitable beds in the non-teaching hospitals in the country as a whole or another 2000 suitable appointments. For a little time, therefore, it may be a tight fit, and it seems doubtful whether there will be enough appointments in general medicine and surgery.

When I qualified I did six months' general medicine and then six months in a chest hospital. It is desirable that all newly qualified men should have six months' medicine if the vacancies are there, but apart from that there should be a wide choice. A responsible house physicianship in tuberculosis would be much better than a supernumerary appointment in a teaching hospital. The rotating internship of three months in different departments has had its day in America, and I hope we shall not introduce it here. It gives a dangerous false sense of competence in surgery and the specialties. A man must occupy a job for six months if he is to learn anything or be useful to his chief.

All this means that hospitals will have to be inspected and approved as suitable for first year graduate appointments.

ts. This offers no difficulty. It is already done on small scale by the Royal Colleges for the F.R.C.S. and for qualifications, and in the U.S.A. it is done on a large scale by the Council on Medical Education. Hospitals of the American Medical Association. An approved hospital must not have less than 85 beds and it have reasonable facilities for radiology, pathology, autopsies, and a proper records system and library. It is usually required that one member of the staff should act as Director of Medical Education, assuring particularly that there is a weekly case conference for housemen and the surrounding practitioners. No hospital in the U.S.A. can hope to get good internships if it is approved, and there has been a tremendous improvement in hospital standards as a result.

Inspection and approval are carried out on much the same lines as the King Edward's Hospital Fund follows in this country. The postgraduate deans could easily arrange similar arrangements using a panel of consultants as visitors. It may take a year or two, but what is a hurry? Shortage of residential accommodation may be a difficulty, but it is not a bar. There is no need for house officers to live in. For the last five years I have run a busy ward of 21 beds with two house officers, junior who lives in and a senior who lives out. Payment must be on the Spens scale. The jobs are no good unless they are responsible and they must be paid a proper wage. One of the weaknesses of the intern system in the American teaching hospitals is that the intern may do no work left for him by the students and the registrars. There is no place in this country for underpaid supernumerary housemen.

I am not alone in thinking that the B.M.A. committee on the Training of the General Practitioner went sadly astray in its recommendations, and one does not know whether to laugh or to cry over its attempts to regulate not only the life but also the thoughts of the family physician. Some of our friends on the committee appear to have walked with kings and lost the common touch. Our young doctors have to spend six years in the medical school, a year in compulsory appointments, and eighteen months or more in the Services. Couldn't we perhaps give them to run their own lives at the end of that time? Osler got into hot water for suggesting chloroform at sixty, but I am sure he was right in saying that "the effective moving vitalising work of the world is done between the ages of twenty five and forty." There is no excuse for a second compulsory year's house appointments after registration, as suggested by the B.M.A., and this consideration should not be allowed to affect the house appointments before registration.

L. J. WITTS

THE CHILD AND HIS HEREDITY

SIR,—Your annotation of July 9 on my paper given at the annual conference of the National Association for Maternity and Child Welfare contains two errors of the kind that can easily be made in reporting the spoken word. As they are points of substance I should be grateful if you would allow me to correct them.

It is stated that in 1937 among children of school age 37 per 100,000 were blind. This should be 1923, not 1937. I was quoting from Prof. Arnold Sorsby's important monograph *The Causes of Blindness in England and Wales*,¹ in which he shows that whereas in 1923 the rate was 37 per 100,000, with one third due to congenital and hereditary causes, by 1948 the figure had been reduced to 21, but that of these two thirds were congenital or hereditary.

Later I am quoted as saying that if the average age of mothers could be reduced by five years, the incidence

of congenital malformations of all kinds would be cut by about half. My actual statement was "if the average age of the mother at the birth of the child were reduced by five years, the incidence of mongolism would be cut to less than half, and there would be an appreciable reduction even if it were not so striking in a number of other congenital defects such as congenital hearts and hydrocephalus."

ACTION IN RHEUMATOID ARTHRITIS

SIR,—Dr. Brasier and Dr. Pugh (July 15) say that they gave intravenous adrenaline to six rheumatoid patients by continuous drip over 3-7 days, with results not superior to the intramuscular route. I would like to suggest that rather less dilute solutions be given intravenously intermittently—i.e., each infusion to take not more than 20 minutes and to be repeated three or four times a day. Such a course of action would be more in line with my experience and might avoid deterioration of adrenaline in weak solution, the solutions being freshly made just before transfusion.

LARYNGEAL VERTIGO

SIR,—I suggest that the explanation for the syndrome termed laryngeal vertigo discussed in your leading article of July 15 is somewhat as follows.

In a person with a long thin neck who suffers from a chronic cough all the veins—unrestricted by much muscle and fat—above the level of the manubrium sterni will become distended during bouts of coughing. The distension will probably be more marked in the large cervical veins whose walls contain the maximum of elastic tissue in the area than in those situated more distally. On the other hand in a person with a short fat neck—where there is much restricting fat and muscle—the total amount of distension of the shorter "large" cervical veins is likely to be small. Furthermore, during bouts of coughing the hypertrophied sternomastoids and anterior scalen and the omohyoids will themselves compress the internal jugulars. The drainage of the cerebrospinal veins will be further restricted, not only in the thorax but also in the abdomen towards which the emphysematous lungs descend and where the large deposits of fat indirectly compress the inferior vena cava when the abdominal muscles contract. The hard jerky series of unproductive coughs against a closed glottis aggravate this feature, which will rapidly increase the distension and in time, produce permanent dilatation of the cerebral veins. Considerable alterations in pressure will thus be produced in veins draining the brain whose nerve tissue has probably been additionally affected by the alcohol. I suggest therefore that an investigation of the cerebral veins, particularly of their calibre, may help to elucidate the aetiology of this disorder.

I. H. MILNER

SIR,—Your leading article of July 15 is of particular interest to me because two weeks ago I saw a case of laryngeal vertigo.

A tall plethoric, obese man, aged 50, was referred to me by his doctor on account of "cough and blackouts." He had had a left lower lobectomy for bronchiectasis in 1948.

He was on holiday in this country from Canada, and one day, when visiting one of our large multiple stores, he had a severe dry coughing spasm which started as a tickle in his throat. He fell to the floor with momentary loss of consciousness. He thought that there had been jerking (convulsive movements) of both his arms and legs, no tongue biting and no incontinence. The attack was followed by a drowsy feeling, he did not actually go to sleep, though he felt he would have liked to have done so.

Incidentally, his blood pressure was 150/95, and both Wassermann and Kahn reactions were negative, but these latter results may have been masked by repeated courses of penicillin for his bronchiectasis.

Three exactly similar attacks followed the first, and all three occurred while sitting in a chair, after a dry coughing bout which was preceded by a tickle in the throat.

Admission to hospital was advised for full neurological investigation, but as he was returning to Canada within the next few days this course could not be pursued, and he was recommended to see his doctor in Canada immediately on his return.

THE "GENERAL ADAPTATION SYNDROME"

SIR,—The enthusiasm with which a London audience is reported to have greeted Dr Hans Selye's recent Heberden oration seems to assure for the general adaptation syndrome a prominent place in future British text books. Your timely publication, last week, of Professor Pickering's thoughtful and penetrating analysis of Selye's contribution to rheumatoid arthritis should help to forestall this possibility, and may also bring to the first enthusiasts some more sober second thoughts.

Undoubtedly Selye's hypothesis has many attractions: it has a background of elaborate experimentation and a mass of apparently supporting literature; it is fascinatingly presented and illustrated with beautiful photomicrographs. It has all the charm of a synthesis, bringing together of a mass of hitherto confusing and apparently unrelated observations. The recent discovery of the effects produced by adrenocorticotrophic hormone (ACTH) and 'Cortisone' in rheumatoid arthritis seems at first sight, to demonstrate its validity.

Yet, as Pickering rightly points out, the great discovery of the Mayo Clinic group "was made quite independently of this hypothesis." It may be well to recall that Selye¹ originally reported that rats deprived of one kidney and also of their suprarenals or thyroid, given only saline to drink and injected with huge doses of deoxycortone (4–6 mg daily) developed within 14–26 days (if they survived) an arthritis resembling "that seen in acute rheumatic fever." Only later did Selye² claim that the joint changes in these rats "might be called an experimental replica of rheumatoid arthritis." There was little in this to suggest, at the time, that a suprarenal glucocorticoid might relieve rheumatoid arthritis.

It is sometimes overlooked that the hypothesis of the general adaptation syndrome (as first fully announced in 1946) conspicuously failed to predict the result of the Mayo Clinic experiment. Surely the acid test of the validity of any hypothesis is: can it predict the results of future observations within its compass? If it cannot do this, it is scientifically worthless.

Looking back on the distant past of three years ago, before the Mayo Clinic discovery, it now seems remarkable that a man of Selye's brilliance did not foresee what was to come and, in his textbook, was still saying³ "it is noteworthy that corticotrophic pituitary extracts frequently produce arthritis in the rat." This observation is now apparently explained by his "factor X."

Following the Mayo Clinic discovery, it seemed almost as though the harmful effects of deoxycortone bore no relation to anything that actually happens in the animal body, particularly since, as Selye⁴ says, deoxycortone "has not been definitely proved to be produced by the adrenal cortex." This difficulty was apparently over-

come by a prominently published⁵ experiment on castrated, partially nephrectomised rats in which naturally occurring mineralo corticoid (deoxoc) was reported to produce, in rats, hypertension and changes, but not, this time, arthritis. The blood pressure was measured by the tail cuff method and "very light ether anaesthesia," which has been elsewhere to have certain disadvantages. So far I know, this experiment has not yet been confirmed. Selye's brilliant technical skill is hard to duplicate, so his experimental observations tend to be taken "as read" by most of his followers.

The general idea of the general adaptation syndrome as now presented is, as I understand it (and I share with Pickering that reservation), that the body reacts to all forms of stress by hypophyseal stimulation of the supranal cortex. As Selye⁶ now says, "all stressors elicit an ACTH discharge." One of his previous statements was less definite: "It must be admitted that the increase in corticotrophin production during stress has never been measured directly, it was assumed to occur only because of the resultant adrenal change."

We are led to believe that under the influence of ACTH (or perhaps "factor X") the adrenal cortex sometimes reacts, for some inexplicable reason, by the production of an excess or "improper balance" of mineralo-corticoids, the result is a host of human ills. Yet how do we know that the cortex ever does put out mineralo-corticoids under stress? As Selye himself has said,¹ "stress causes an increased elimination of glucocorticoids" but a concomitant increase in mineralo-corticoids is postulated almost entirely on indirect evidence.

I hope, Sir, that I have said enough to indicate how tenuous the evidence is on which the whole elaborate structure of the general adaptation syndrome is founded. Even supposing that some of Selye's deductive speculations ultimately prove to be right, what do they tell us of practical value that we do not already know from other sources?

Many students, postgraduates, even teachers, are now spending long hours searching through the tangle of Selye's voluminous writing in quest of some essential truth which they feel must be there. I think that we should advise them to spend their time in better ways.

As Pickering rightly warns, "the history of medicine shows how great is the tendency for a tentative and imperfectly documented hypothesis to assume the guise of a so called fundamental principle."

A. P. MEIKLEJOHN

THE SIGNIFICANCE OF CORTISONE

SIR,—It is with some hesitation that I write to offer a few criticisms of Professor Pickering's article of July 15 on the significance of the discovery of the effects of 'Cortisone' on rheumatoid arthritis. In his review of worn out hypotheses of this century he suggests that psychosomatic concepts of the aetiology of diseases should be dismissed as the focal sepsis theory has already been dismissed by all critically minded students of medical progress. He denies the existence of the widely accepted correlation between particular personality types and the occurrence of particular diseases, of which perhaps the best examples are ulcerative colitis, migraine, hypertension, and peptic ulcer. He ignores the many instances in which the onset of various diseases such as thyrotoxicosis, ulcerative colitis, and haematemeses from peptic ulcer may follow closely upon severe emotional shock. In dealing with the effects of psychotherapy he is more cautious, qualifying his dismissal with the word

- 1 Selye H. *Silverstone O. Hall C. E. Leblond C. P. J. Amer. med. Ass.* 1944 124 201.
- 2 Selye H. *Brit. med. J.* 1949 II 1129.
- 3 Selye H. *Textbook of Endocrinology*. Montreal 1947. p. 54.
- 4 Selye H. *Brit. med. J.* 1950 I 203.

5 Selye H. *Ibid.* p. 1387.

6 Selye H. *Factors Regulating Blood Pressure*. Jo. John & Co. Foundation Publications. New York 1954. p. 85.

Idom and "reputable" That he is out of synch and perhaps out of touch with present day conceptions of the status of psychosomatic factors in cases of hitherto unknown pathology is apparent from the way he couples the rheumatic diseases in which few would suggest that such factors are of great importance with ulcerative colitis and peptic ulcer in which their role is accepted.

In considering Hench's original interest in the effect of pregnancy and jaundice on rheumatoid arthritis and his work of wider scope I await with interest any bit which may be thrown on the striking negative relation which exists between pregnancy and peptic ulcer, and the effect of cortisone on chorea in view of the occasional occurrence of a severe form of this disease in pregnancy.

G. R. VINNING

TRIBUTE TO PROF. MATTHEW STEWART

SIR—Prof. Matthew J. Stewart is retiring at the end of the summer after holding the chair of pathology in this university for 33 years. He has made notable contributions to pathology and taken a leading part in the affairs of the Pathological Society whose journal he has edited for 16 years.

It has been decided by his friends to commemorate his unique service by the foundation of a lectureship which shall bear his name and afford an opportunity at least once in every generation of students for a distinguished pathologist to visit Leeds and to discuss some important development in pathology. In this way the name of Matthew Stewart would be kept in memory. It is also hoped to present a bronze medalion portrait of Professor Stewart to the Medical School.

Subscriptions may be sent either to the National Provincial Bank, 2 Park Row, Leeds or to the hon. treasurer, the School of Medicine, Leeds 2. Cheques should be made payable to the "M. J. Stewart Retirement Fund."

INOCULATION CERTIFICATES REQUIRED ABROAD

SIR,—From somewhat inconvenient experiences during my recent world tour, I have realised the necessity of paying strict attention to the various regulations made by Eastern Governments regarding vaccination and inoculations.

Instructions on this matter are continually being altered without notice and it is time that some uniform system was evolved. I understand that the World Health Organisation is giving some attention to the matter. In addition to vaccination some governments insist on protection against yellow fever and typhus, therefore it is probably safest to be protected against them all. As regards cholera, it should be emphasised that the Egyptian government lay more stress upon this than any other, and may on occasion actually segregate a person who is not thus protected. This inoculation must have been performed six days before landing on Egyptian territory. These regulations apply to passengers in transit as well as to visitors to Egypt. Little or no attention is paid to inoculation with TAB, but smallpox vaccination is considered to be of paramount importance.

Many governments require inoculation and vaccination certificates to be authenticated and stamped by a government medical officer or medical officer of health. The reason for this is to ensure that the certificate has

been issued by a reputable qualified doctor. As it is not always certain at any time which governments do insist upon this authentication it is in the passenger's interests for all certificates to be officially stamped.

In view of these complications I am suggesting that the British Medical Association secretariat should maintain an up-to-date dossier of information on the requirements of all the various governments. They would then be in a position to advise medical practitioners as to what instructions they should give to their patients who are going abroad by sea or by air. I also think that a notice on the lines of my second and third paragraphs should be distributed to all doctors for their information.

As things stand, the wisest course for intending travellers is to consult the officials of the airline concerned who generally have the latest information.—L.D.L.

R.A.M.C. WAR MEMORIAL

SIR,—The Roll of Honour of all ranks of the Royal Army Medical Corps who gave their lives during the Second World War (Sept. 3, 1939, to May 8, 1946) is now complete and copies have been sent to all the next of kin with whom we have been able to get into touch.

I shall be glad to send a copy to any who, owing to a change of address or other cause, may not have received the original notice.

The roll is included in an illustrated booklet describing our Book of Remembrance, the Memorial Window and other Corps memorials in Westminster Abbey and its precincts, and will be sent to any of your readers who are kind enough to send a donation to our fund, which is devoted to helping all ranks of the R.A.M.C. who took part in the war and their families.

Medicine and the Law

Legacies to N.H.S. Hospitals

ESTATEPLANS it seems are disinclined to leave their money to hospitals which have been handed over to the State. Their dispositions when they seek to bar anything like a nationalised hospital from obtaining any benefit, are making work for the judges who have to interpret their wills. Two cases reported in the *Times* of July 7 illustrate the kind of difficulty encountered.

One case concerned the will made by the widow of Sir John Bland Sutton. She directed her trustee to hold an endowment fund (amounting to over £23,000) on trust after providing for a Bland Sutton scholarship at the Royal College of Surgeons to pay the income to the Bland Sutton Institute of Pathology at the Middlesex Hospital. If the institute ceased to be carried on, or if its name was changed, or if the Middlesex Hospital were nationalised or passed into public ownership, then the trustee was to transfer the endowment fund (both capital and income) to the Royal College of Surgeons. The question for the court was whether any of those events had happened, and, if so, at what date.

Mr. Justice Danckwerts came to the conclusion that none of them had happened yet and therefore the college was not yet entitled. He scrutinised the various relevant sections of the National Health Service Act of 1946 for guidance, bearing in mind that the Middlesex was a teaching hospital, and that the Bland Sutton Institute was part of a medical school at the date (July 5, 1948) when the Act came into force. In spite, he said, of any popular view which might have emerged from the "possibly uninformed discussions" accompanying the passing of the Act, he was of the opinion that the old Middlesex Hospital had not as a whole been nationalised.

or passed into public ownership, part of its property—namely the medical school (the most relevant part for the purposes of Lady Bland Sutton's will)—had been transferred to, and vested in, a corporate body (the council of the school) which was neither nationalised nor publicly owned. The institute and its work continued though the institute might now be administered by a differently constituted authority.

The other case arose over the will of Mr J E Frere, who died in Hampshire early in 1949. He bequeathed a legacy of £6000 to the Fleet and District Hospital if still at his death conducted on the voluntary system and not taken over by the State. There was general agreement that, as the hospital had come under State control, this legacy failed. Mr Frere had also bequeathed his residuary estate to the same hospital "for endowment purposes." The first question for the court was whether the condition which had been expressly attached to the frustrated gift of £6000 was to be tacitly attached also to the bequest of the residue. Was the bequest of residue valid, and if so, did the money go to the Farnham Group Hospital Management Committee or to the South West Metropolitan Regional Hospital Board? If the bequest was not valid the residue would presumably go to the

next of kin. Mr Justice Wynn Parry found 'obliged "with considerable reluctance" to hold no condition was attached to the bequest of the and therefore the money would go to the body now standing in the shoes of the Fleet and District Hospital. Ingenious argument was put forward on behalf of next of kin. Counsel contended that the gift to hospital could not be valid unless it was, in the legal sense, charitable. The gift of residue, having been made "for endowment purposes," ought to fail because the hospital had ceased to be a charity. The judge, however, followed a recent decision by Mr Justice Harman (in the case of Deans' Trusts) to the effect that a hospital does not cease to be a charity because of the operation of the National Health Service Act. Moreover, section 59 of the Act enables the new hospital management committees and regional hospital boards to accept gifts "for purposes relating to hospital services" or for research. Thus, in spite of the reluctance expressed in the earlier part of Mr Frere's will to endow hospital services which are provided by the State and not under a voluntary system, the new régime will benefit and the next of kin is disappointed.

Parliament

The Medical Bill

THE Medical Bill was considered in committee in the House of Commons on July 14. On clause 2, which enables the General Medical Council to fix a period of not less than twelve months internship before registration, Sir HUGH LUCAS TOOTH moved an amendment providing that no confirmatory order should be made by the Privy Council unless a draft had been laid before Parliament and had been approved by resolution of each House. Mr ANEUKIN BEVAN, Minister of Health, accepted this amendment in substance though not in form. He also accepted in principle an amendment, by Mr SOMERVILLE HASTINGS, that where physical disability rendered an appointment in surgery or midwifery impossible the council might accept an equivalent period of satisfactory service in medicine or in a health centre in lieu thereof.

THE COMPULSORY INTERNSHIP

Commander A H P NOBLE raised the case of those whose medical studies were interrupted by the war, and who would otherwise have qualified before the Bill came into force. Many of them were very keen to get into practice as soon as possible. Dr BARNETT STROSS thought that married men might be given an opportunity of opting out of the year's internship. Moreover not everyone wanted to be registered in the full sense. If a man had completed his medical studies and obtained his degree, he might wish to work as a physiologist for the remainder of his life, or go on to biochemistry. If such a man wanted to come back to practise he could do so by serving a year in hospital. Also he thought that some safeguard should be given against the possibility of favouritism in regard to the certification of "satisfactory service."

Mr HUGH LINSTED said he had no doubt that the Minister had in mind some period of time before the new arrangements were brought into operation, so that there could be no suggestion of a breach of faith with existing medical students. As for the period of internship, he was quite sure that the Privy Council and the G M O would not use the important power given to them in any callous way, but, if the Minister could indicate that there was a limit of a year in his mind, that would remove any fear that the period could be extended indefinitely. Medical students were anxious to know what their position would be if a certificate of satisfactory service was refused them. Would there be a right of appeal, or would they be completely at the mercy of the hospital or the qualifying body under whom this period of internship was served?

Dr A D D BROUGHTON urged the Minister to give most careful consideration to the cases of hardship which might arise if this clause was passed unamended. He quoted the case of a medical student who was a retired barrister. His age could be judged by the fact that he would draw his post-war credit very soon. The man wished to spend the remainder of his life as a medical missionary in India, but if he had to put in an extra year's work of intern duties after qualification all his plans would be upset. The British Medical Students Association desired that all present medical students should be exempted from the requirement of internship. Dr Broughton did not think it would be necessary to go so far as that, but he hoped that some right of appeal would be allowed to those who would suffer by the operation of the Bill as it stood at present.

Surgeon Lieut.-Commander REGINALD BENNETT supported Dr Stross's plea for those who might not intend to practise clinical medicine after finishing their training. He also wanted to know what would constitute "unsatisfactory service." Dr H B MORGAN also favoured a right of appeal. Mr IAIN MACLEOD pointed out that when the new system started there would be a wastage for one year at least, of general practitioners in the National Health Service. It was for Parliament to discuss at what point the service could afford that wastage. It might be expedient for a limited period to allow doctors after qualification to go into practice in under-doctored areas, to allow them to act as assistants to group practices, or work in the health centres where it was hoped would increase in number.

Mr HASTINGS said there were very few cases in which a surgeon or physician in charge would feel justified in saying that a man's service was unsatisfactory, and if the right of appeal was conceded there would be fewer. Mr BEVAN, in reply, said he wanted to remove any idea that the Minister of Health was in this country accepting responsibility for the content and management of medical education. He was not. It was necessary to have a sense of proportion and keep an even balance between the legitimate affairs of the medical student and the requirements of the public. It was not the duty of Parliament to let loose upon the community what might be regarded as under-educated doctors, or to protect individual doctors from what might appear to be hardship. But the implementing of the Government's proposals meant that the State intervened in altered the plans which the private citizen made for himself when he intended to go in for medical training. Therefore Parliament must try to see that the arrangements made bore as little harshly on the citizen as consistent with the public interest.

The new requirement was not going to be upon the student immediately, it would take between a year and two years to make the arrangements.

It would be quite improper for the State to say that a doctor did not be fully registered and enter into general practice without serving an intern year in an approved establishment and at the same time to fail to find a place for him. The two must go together. The time starting the scheme could not be fixed until the Government had reviewed the establishments and made posts available. He thought that with the passing of another year or two most ex-Servicemen would have the medical schools and therefore there would not be very much hardship in that connection. Besides providing posts in hospitals they had also to ensure that financial hardship was mitigated as far as possible. It was therefore proposed to create posts paying a salary of £350 a year for the first six months, £400 a year for the second six months, with a tuition of £100 for board and lodging. These amounts were fairly generous sums. Indeed it was more money than many general practitioners earned in their first year of general practice at any rate before the war. It was not the present intention to make any advances for married students, but the point would be there examined to see if anything more could be done in that regard.

Dr CHARLES HILL asked the Minister whether this could be technically applied at the beginning of a provisional post for entry into the National Health Service. He said it was the superannuation implication which he had in mind.

Mr BEVAN said this was a very special point, but these sums must be carried on the Ministry of Health Vote and not on the University Vote or the Education Vote. Those doctors who were provisionally registered could be employees of the hospital and he thought it followed almost inevitably that the term of service in the National Health Service would date from the beginning of the internship. But he hoped that Dr Hill could not keep him strictly to that. For all purposes connected with his work in the hospital and any work which might be given to him arising out of his internship, the intern was a doctor.

Some people had asked whether it was fair to a person who had made plans based on the assumption that his training would come to an end at a certain time to add another year, but if they were to carry out the recommendations of the Goodenough Committee they must sign at some point or another. If they began when the student came in that would mean that the scheme could not come into full operation for seven or eight years. He hoped too that he would not be pressed to give concessions on grounds of hardship. Why should they send out into general practice one doctor who was less well trained than they thought he ought to be, that would be a detriment to the patient and not good for the doctor. When the date fell it should fall upon all medical students as otherwise the exceptions would go through life with a black mark.

There was a good deal of anxiety about the question of satisfactory service, and that could be understood because it was so difficult to define. Nevertheless it was ready in use. He was informed that it was similar to the signing of certificates now required to show satisfactory attendance at courses of instruction before a student could sit for his final examinations. These certificates covered conduct as well as attendance. They presented the opinion of all the people under whom a student had worked. Similarly, certificates of satisfaction would reflect a number of opinions and there would be no possibility of victimisation by a single individual on personal grounds. The certificate itself is given by the licensing body—the medical corporation immediately concerned. He hoped, therefore, that he would not be pressed to give a right of appeal. They would not have an appeal against a board of examiners. Mr BEVAN hoped that he had reassured the student at he was not putting himself in the hands of someone who might have a spite against him. It must be remembered that when a person reached this stage he was provisionally registered. It was not the intention to put up another hoop through which he had to jump, to give him a year's experience in association with specialists with a diverse kind of hospital work so that when he became a general practitioner he would be a

better craftsman. There was no reason why, if an intern had "boomed it," he should not have another opportunity in another hospital to serve another year.

The present intention was to bring the arrangements into operation everywhere at the same time. The power to vary the period was merely for the purpose of emergency.

Exemption of the "deviationists" who decided to go into biochemistry and other things, was in Mr BEVAN'S opinion impracticable. If a man qualified and then asked to be exempted from the intern year on the ground that he did not wish to practise, Mr BEVAN thought he would be a very queer kind of medical animal. They would not know what to do with him afterwards.

Surg. on Lieut. Commander BURNETT: The universities are full of them.

Mr BEVAN said that might be so, but so far as he knew nothing at present prevented them from practising clinically if they wanted to. Would such persons say that they did not wish to be put on the Medical Register? He did not see how a provision could be framed putting them in suspense as it were. They must come down on one side or the other.

Mr HASTINGS moved an amendment providing that a person provisionally registered under the Act should have all the duties and privileges of a registered medical practitioner but only while serving in the approved hospital or institution to which he was attached. He said that while serving in a hospital the intern should be able to order dangerous drugs and when he was the only person who had attended a patient to sign a death certificate. Everybody including the public should know exactly what were the powers of the provisionally registered doctor and these should not be left to be defined by regulations.

Dr MORRIS thought the amendment would do the health service harm and the doctor an injustice if his duties and privileges were limited only.

Dr HILL said that if the intern were to be regarded as a fully registered practitioner for a wide range of purposes this year of training would fall into disrepute. It should be regarded as an essential part of medical education. I say that to equate the provisionally registered with the permanently registered man merely leaving an interval of time to pass between them seems to suggest that the standard of registration is reached with provisional registration and that this final year is a kind of burden imposed by the State. Until they had seen the picture of the provisional year and the form that the internship took, he doubted if they were in a position to decide that all the privileges of registration should go with provisional registration.

Mr BEVAN said that here he was in fairly general agreement with Dr Hill. It was difficult to describe this intern year properly, but its equivalent did exist in other academic fields. Unless they were careful it would lose its status. It was not suggested that the doctor was not fully educated when put on the provisional register, but it was held that a year's satisfactory experience of this sort was necessary for his final equipment as a general practitioner. In the institution he could sign death certificates and give drugs if it was appropriate for him to do so in the circumstances of the case.

The amendment was by leave withdrawn.

DISCIPLINARY PROCEDURE OF G.M.C.

Mr BEVAN accepted in principle an amendment moved by Lieut. Colonel WALTER LELLIOT covering with a statutory provision the preliminary stages of the investigation of complaints and ensuring that a person taking part in the "screening" should not take part in the judging.

Dr HILL moved an amendment to secure that what he said was the almost uniform practice of the General Medical Council—that there must be a statement by the complainant—should become the uniform practice. He said that there had grown up in the last few years a habit on the part of Government departments, including the Ministry of Health, of not complaining but sending the papers along in the hope that the G.M.C. might do something about it. The object of the amendment was that, whether the complainant be an individual, a body

or a Government department, there should be a formal complaint to the G M C

Mr BEVAN said he must resist the amendment. It meant that the disciplinary committee of the G M C would be an arbitrator between the doctor and a Government department. That placed the department in an entirely false position. It did not follow that the Ministry of Health in this case should come to a conclusion about the doctor at all. It merely meant that in the exercise of the administrative duties placed upon him under the health statutes the tribunal had brought to light evidence that would appear on the surface to be evidence that the G M C should see in order to make up its mind whether or not it should consider putting its disciplinary machinery into motion. That seemed to be a reasonable protection for the public, but it would not be reasonable to expect the Minister of Health himself to have a preliminary investigation on matters falling within the jurisdiction of the G M C's disciplinary machinery and to pre-hear the case.

After further debate, Dr HILL said that what had happened was this. Allegations had been brought against a practitioner and they had gone through the Minister's own machinery and culminated in the rejection by the tribunal of the allegation. Then the papers, which could only relate to matters within the field of the Minister's own tribunal, had been sent to the G M C. In other words, there having been failure to secure the lesser verdict of removing the man from the service, they had tried the other way to obtain the higher verdict of removing him from the Register altogether. That was the point he hoped the Minister would look into.

Mr BEVAN said he doubted very much whether the case was as Dr Hill had described. However, he would look at the matter, but he hoped that he would not be pressed too far, because once a Government department was asked to formalise evidence against the practitioner they were discriminating against the general practitioner in the most dangerous way. He hoped the amendment would not be pressed at this stage.

Further consideration of the Bill was adjourned.

Disease in the Colonies

In the House of Commons on July 11, Mr J S ARBUTHNOT drew attention to the relative lack of progress in malaria control in Africa. With the aid of demonstration antimalarial teams formed by the World Health Organisation, 15 million people had been protected in Brazil, 500,000 in British Guiana, and 4 million in Venezuela, 5 million people had been protected under one of the Indian schemes, and 6 million in Ceylon. In Ceylon the death-rates per 1000, which averaged about 21 in the ten years before 1947, had fallen to 13.2 since spraying with DDT had begun. The Colonial Empire in Africa presented a distressing contrast. There had been some small schemes but they were confined in the main to the towns.

Mr T F COOK, under-secretary of state for the Colonies, in reply, said that since 1940 over £600,000 had been provided from Colonial Development and Welfare Funds for control schemes in these territories. More than £250,000 had been devoted from the same source for research into insecticides and for drainage and irrigation. In addition, considerable amounts had been provided by the Colonial governments themselves. In large centres malaria risk had been reduced to a negligible level and there had been steady progress in smaller centres. Malaria control, however, presented greater difficulties in Africa than elsewhere, because there were two types of malaria-bearing mosquito. One bred under shade and the other in the open, thus neither bush clearance nor artificial shade was efficacious. Another difficulty had been that antimalarial drugs did not have the same conspicuous success in Africa as they had in other parts of the world, but a method of thoroughly efficacious treatment had now been worked out. Colonial governments were aware of the many types of assistance provided by W H O, and he was sure that there would be a steady increase in the number of requests to the organisation. An international conference on malaria which was to be held in East Africa next November and December, under the joint auspices of

W H O and the Commission for Technical Co-operation in Africa South of the Sahara, and the problem of malaria in Africa would then be exhaustively studied.

On July 12 Mr JAMES GRIFFITHS, secretary of for the Colonies, said that over the past decade had been striking improvements in the health of Colonies. This was largely due to the control of. The Government were also determined that every method should be brought to bear on tuberculosis, incidence of which in the Colonies gave rise to much concern. He now had a special consultant tuberculosis and with his assistance plans had been for a co-ordinated attack on the disease throughout Colonial territories.

Mr M PHILLIPS PRICE expressed concern about effect of medical and welfare work on the population problems of both Africa and Asia. In a large part of Africa one African peasant produced food for two no more. Mr Price believed, however, that it might be quite possible to increase food supplies by developing a communal co-operative method of farming based on the tribal system.

Dr H B MORGAN said a very fine piece of work had been done for nursing and the health services in the West Indies, but he hoped the Government would do something to reduce the amount of capitalistic exploitation in those Colonies. Disease was rampant there—only venereal disease, which the foreigners brought but malaria and tuberculosis.

On July 12 the Royal Assent was given by commission to the Midwives (Amendment) Act.

Obituary

EDWIN MATTHEW

M A. ABERD, M D EDIN, F R C P E

Dr Matthew, emeritus professor of clinical medicine in the University of Edinburgh, who died on July 4, was a distinguished member of his school. He was born in Aberdeen and attended the university there but his whole medical life was associated with Edinburgh. In 1897 he graduated M B, with first-class honours, and he obtained the M D, degree with gold medal in 1908. While an undergraduate he gained Vans Dunlop scholarship, and on graduation he awarded the Ettles scholarship as the most distinguished student of his year. He was house-physician to Sir Thomas Fraser in Edinburgh Royal Infirmary, and then held a similar appointment in the Edinburgh Royal Hospital for Sick Children. He became a member of the Royal College of Physicians of Edinburgh in 1902, was elected a fellow four years later.

He was appointed assistant physician to Edinburgh Royal Infirmary in 1909, and was physician in charge of wards from 1921 to 1930, during the last two years holding the Moncrieff Arnott chair of clinical medicine. In his earlier years he held the post of physician in Leith Hospital. For five years he represented the Royal College of Physicians of Edinburgh on the General Medical Council.

Matthew was recognised as an outstanding teacher by all associated with him, especially by that body, the students. He held the view, on which many of us are agreed in theory, but to which he rigidly adhered in practice, that the teaching of undergraduates and postgraduates is entirely different. To the latter alternative arguments and theories must be presented so that they may be in a position to make their own choice, but undergraduates have not the necessary knowledge, and their teaching should be simple, unconfusing, and dogmatic. On this method Matthew's success as a teacher was based, and by it he earned the gratitude of his students.

In private practice successfully, though perhaps unconsciously, he acted fundamentally in the same manner. His advice to patients was clear and definite and he was not prepared to modify it, or to under-treat except on the lines which, he was confident, were in the best interests of the patient. A few doctors were annoyed by this determination, but his

Dr G A Smart has been appointed reader in medicine

University of Liverpool

On July 8 the honorary degree of LL.D. was conferred on Sir Henry Cohen, F.R.C.P., professor of medicine at Liverpool University and president elect of the British Medical Association. Dr E A Gregg, chairman of the council of the B.M.A., and Dr C O Stallybrass, former deputy medical officer of health for Liverpool

University of Dublin

Dr Frederick Stanley Stewart has been appointed to the chair of bacteriology and preventive medicine, in succession to Prof J W Bigger, whose retirement at the end of September we announced on July 1

Dr Stewart who is 35 was educated at Wesley College and at Trinity College Dublin. He distinguished himself first in philosophy gaining in 1937 a foundation scholarship and first class moderatorship in mental and moral science. In the medical school he obtained the Begley studentship, the Stewart scholarship, the Cunningham medal for anatomy, and the Fitzpatrick scholarship. Graduating M.B. in 1942 he took the M.D. in 1944 and the M.R.C.P. in 1946. He held the post of house physician in Dr Stevens Hospital and in the National Children's Hospital and for seven years has been assistant and lecturer in bacteriology in Trinity College. In 1949 with the aid of a grant from the Medical Research Council of Ireland, he visited the U.S.A. where he spent six months in the study of virus technique. For most of the time he worked under Prof T Francis Jun., at the Virus Laboratory University of Michigan. He has published papers on Rh immunisation and on the antigenic modification of red cells by periodate and has taken an active part in teaching in the department of bacteriology and preventive medicine.

British Medical Association

Katherine Bishop Harman prize—The council of the association is prepared to consider an award of this prize (£75) in 1951

The purpose of the prize is to encourage study and research directed to diminishing and avoiding the risks to health and life that are apt to arise in pregnancy and childbearing. Any registered medical practitioner in the British Empire may compete. Inquiries should be addressed to the secretary of the association, B.M.A. House Tavistock Square London W.C.1

Conference on Food-poisoning

A conference on food poisoning and its prevention is to be held, under the chairmanship of Sir Wilson Jameson at Olympia, London, on Aug 31. It is expected that the conference, which is being arranged by the Central Council for Health Education, will be attended by representatives of the food trade and from local authorities throughout Great Britain and Northern Ireland. The speakers will include Prof G S Wilson, Miss Betty Hobbs F.R.D., Dr Bernard Schlesinger, and Dr E K Macdonald

Order of the Hospital of St John of Jerusalem

The following appointments have been made

Officer (brother)—Dr H S Taylor Young
Serving brothers—Lieut Colonel O L Appleton, Lt Dr H W Round Dr D A Brigg, Dr G K Arthur
Serving sister—Dr Eleanor D Blunt.

International Hæmophilia Society

A delegate of this society is attending the International Conference of Social Work in Paris from July 23 to 28. It can be addressed c/o Secretariat, British National Sorbonne, Paris

Princess Tsahai Hospital

This hospital, which is being built in Addis Ababa, nearing completion, and the honorary medical officers are prepared to engage staff. It is hoped that the hospital will begin this year. The hon. secretary— Sylvia Pankhurst, 3, Charteris Road, Woodford, Essex.

Blood-donors

Gifts of blood to hospitals in England and Wales, the National Blood Transfusion Service totalled during the first three months of this year—the number since the war. Over 23,600 more donors for service in the quarter, bringing the total strength to 377,704. Another 220,000 donors are needed to keep up the steadily increasing demands of hospitals and to call on the individual donor.

The Blind in Scotland

There were 8854 registered blind persons in Scotland at the end of March, compared with 8596 in 1949 and 8014 (highest recorded figure) in 1939, and 77% of them were fifty years old. Blindness among children continues to decrease: there were 170 blind children under sixteen, compared with 195 in 1939.

American "Mercy-killing" Case

Last March Dr Hermann N Sander, a new Hampshire practitioner, was acquitted of a murder charge arising from his admission that he had introduced air into the circulation of a woman dying of cancer. At the trial it was argued on the defence that the air had not entered the vein, and that at the time of the attempted injection the patient was already dead (see *Lancet*, March 18, p 524). After the acquittal the State Board of Registration suspended Dr Sander's licence to practise, but this licence has now been restored.

International Federation of Physical Medicine

At a meeting recently held in London it was decided to constitute the International Federation of Physical Medicine. The objects of this body are (1) to promote on an international basis the study and practice of physical medicine in the widest sense of the term, and (2) to hold international conferences in this subject. An interim committee was appointed as follows: chairman, Dr Frank Krusen (Mayo Clinic, U.S.A.), vice chairman, Dr Svend Clemmesen (Copenhagen), hon. secretary, Dr Philippe Bauwens (London), members, Dr W S Tegner (London) and Dr Hugh F (London). The temporary headquarters of the Federation will be in London (c/o the British Association of Physical Medicine, 45, Lincoln's Inn Fields, London, W.C.2), and the first congress will if possible be held in London in July 1951.

Mr O F C Bromfield, F.R.C.S., has retired, on medical grounds, from the editorship of the *Chemist and Druggist*. He has been connected with the journal for over twenty years and has been editor since 1940.

In the final of the Leeds medical golf competition for the Moynihan challenge cup, held at Alwoodley Golf Club, July 9, Dr L L Hurwicz beat Dr John Douglas 5 & 3 (36 holes).

NEUROSURGICAL TREATMENT OF PERSISTENT PAIN*

J. C. WHITE

M.D. Harvard U.S.A.

ASSOCIATE PROFESSOR OF SURGERY, HARVARD MEDICAL SCHOOL, CHIEF OF NEUROSURGICAL SERVICE, MASSACHUSETTS GENERAL HOSPITAL, BOSTON, U.S.A.

PAIN, although not a malady in itself, is a common denominator of many medical and surgical conditions. In trauma or acute disease it often serves a valuable purpose by warning the victim of his danger. In the neurologist and in many chronic diseases it is often first recognised as it becomes a painful deterrent. In these circumstances if there is persistent pain which cannot be relieved by direct surgical attack on the pathological lesion itself or by ordinary medication with of narcotic drugs, relief can often be obtained only by surgical interruption of sensory pathways. If surgery withheld the sufferer is in fact doomed to narcotic addiction, physical deterioration or even suicide.

The interest shown in developing the technique of having this type of pain by surgery varies a good deal in different clinics. In the Massachusetts General Hospital we have had a very stimulating opportunity of treating many forms of severe pain. The patients are referred us about the time that heavy doses of morphine become necessary, provided it is felt that the patient has more than a month or two to live. The neurosurgeon must learn the possibilities and limitations of surgical control of pain, that ineffective mutilating procedures can only make matters worse and the symptoms more difficult to deal with, and that once the patient has become a narcotic addict even the most skillfully planned and executed operation may not rid him of his complaints.

In the past fifteen years my associates and I have performed over 1100 operations for the relief of otherwise intractable pain of one form or another, and I shall review here the lessons we have learned. This work has been the common effort of many surgeons of the Massachusetts General Hospital staff, and my personal cases make up a relatively small proportion. In a single lecture it is impossible to include all varieties of neurology and their relief by neurosurgery, so I shall limit my remarks to the three operations which have interested us most—cordotomy, sympathectomy and prefrontal leucotomy—and shall discuss their relative merits and limitations.

INTERPOLAR CORDOTOMY

Spiller had noted that loss of appreciation of pain and euphoria resulted from a lesion in the opposite anterolateral column and in 1912, at his suggestion, darton performed the first cordotomy for the relief of pain (Spiller and Martin 1912). Subsequent cordotomies have been made usually in the upper thoracic region, less often in the upper cervical region. Current textbooks of neurosurgery are responsible for the idea that the depth of a cordotomy incision need be only 3 mm. from the line of the dentate ligament ventrally towards the anterior roots. Such a limited incision rarely produces complete analgesia above the lumbar dermatomes. Electrical stimulation during operations under local anaesthesia has shown that axons subserving pain are scattered widely over the anterolateral quadrant, and the examination of post mortem material has taught us that it is necessary to divide virtually the whole anterolateral quadrant to secure a high level of analgesia (see figure).

We tell the patient what we are trying to achieve and we perform these operations under procaine infiltration

supplemented by light thiopentone and nitrous oxide anaesthesia. When the incision in the cord has been made the patient is allowed to wake and the level of analgesia is checked. Often successively deeper incisions are needed to secure a satisfactory high level. All perception of sharpness or disagreeable sensation or repeated pricking with a pin must be lost. A high degree of hypalgesia will not suffice.

A patient had severe pain in his legs as a result of chronic arthropathy of the coxal joints. On the left he had sensory level at the level of the umbilicus. He was operated on under local anaesthesia and the level of the sensory level was raised to the level of the umbilicus. The level of the sensory level was raised to the level of the umbilicus. He was operated on under local anaesthesia and the level of the sensory level was raised to the level of the umbilicus. He was operated on under local anaesthesia and the level of the sensory level was raised to the level of the umbilicus.

In time the level of analgesia usually always falls several segments, occasionally to a much greater extent, and hypalgesia is substituted for analgesia. This process may pass unnoticed, but in some cases it is noticed. A high degree of hypalgesia is easily taken for analgesia. Even if the patient fails to recognise that single pricking or the scratch of a pin is sharp this does not prove that analgesia is complete. On excitation by rapidly repeated pricks, it is often found where this stimulus evokes a disagreeable response. When this has occurred we have found a second deeper cordotomy effective in two thirds of the cases. Half of the sensory level has been most common in the amputation stump neurologists, particularly in those of the upper extremity where the spinothalamic tract has been divided at the level of the first cervical segment or in the medulla. On the other hand, as a result of faulty surgical technique the level of analgesia achieved may be insufficient and failures and disappointments may result.

It is fortunate that even the most extensive transections of the anterolateral quadrant produce relatively few complications (table 1). To our way of thinking, the risks of cordotomy are so slight in comparison to the psychic damage of leucotomy that we favour its trial on one side at least, if there is any reasonable chance of success.

Cross-section of spinal cord at level of cordotomy at 2nd thoracic segment (Weigert-Pal x 10). There was hypalgesia to xyphoid and analgesia to umbilicus. Relief of contralateral pelvic and leg pain from carcinoma of colon was complete. There was no bladder complication or leg weakness. The patient died of uraemia from ureteral compression. (This illustration demonstrates that even a very complete transection of the anterolateral quadrant may at times not result in a high level of analgesia.)

NEUROSURGICAL TREATMENT OF PERSISTENT PAIN*

J C WHITE

MD Harvard, FACS

ASSOCIATE PROFESSOR OF SURGERY, HARVARD MEDICAL SCHOOL, CHIEF OF NEUROSURGICAL SERVICE, MASSACHUSETTS GENERAL HOSPITAL, BOSTON, U.S.A.

PAIN, although not a malady in itself, is a common nominator of many medical and surgical conditions, and in trauma or acute disease it often serves a very useful purpose by warning the victim of his danger. In the neuralgias and in many chronic diseases as soon as first recognised, it becomes a purely destructive factor. In these circumstances if there is persistent pain which cannot be relieved by direct surgical attack on the pathological lesion itself, or by ordinary medication with narcotic drugs, relief can often be obtained only by surgical interruption of sensory pathways. If surgery is withheld, the sufferer is frequently doomed to narcotic addiction, psychical deterioration, or even suicide.

The interest shown in developing the technique of relieving this type of pain by surgery varies a good deal in different clinics. In the Massachusetts General Hospital we have had a very stimulating opportunity of treating many forms of severe pain. These patients are referred to us about the time that heavy doses of morphine become necessary, provided it is felt that the patient has more than a month or two to live. The neurosurgeon must learn the possibilities and limitations of surgical control of pain, that ineffective mutilating procedures can only make matters worse and the symptoms more difficult to deal with, and that once the patient has become a narcotic addict even the most skillfully planned and executed operation may not rid him of his complaints.

In the past fifteen years my associates and I have performed over 1100 operations for the relief of otherwise intractable pain of one form or another, and I shall review here the lessons we have learned. This work has been the common effort of many surgeons of the Massachusetts General Hospital staff, and my personal cases make up a relatively small proportion. In a single lecture it is impossible to include all varieties of neuralgia and their relief by neurosurgery, so I shall limit my remarks to the three operations which have interested us most—cordotomy, sympathectomy, and prefrontal leucotomy—and shall discuss their relative merits and demerits.

ANTEROLATERAL CORDOTOMY

Spiller had noted that loss of appreciation of pain and temperature resulted from a lesion in the opposite anterolateral column, and in 1912, at his suggestion, Martin performed the first cordotomy for the relief of pain (Spiller and Martin 1912). Subsequent cordotomies have been made usually in the upper thoracic region, less often in the upper cervical region. Current textbooks of neuroanatomy are responsible for the idea that the depth of a cordotomy incision need be only 3 mm., from the line of the dentate ligament ventrally towards the anterior roots. Such a limited incision rarely produces complete analgesia above the lumbar dermatomes. Electrical stimulation during operations under local anaesthesia has shown that axones subserving pain are scattered widely over the anterolateral quadrant, and the examination of post mortem material has taught us that it is necessary to divide virtually the whole anterolateral quadrant to secure a high level of analgesia (see figure).

We tell the patient what we are trying to achieve and we perform these operations under procaine infiltration,

* A Macarthur Postgraduate Lecture in the University of Edinburgh, delivered on May 10, 1950.

supplemented by light thiopentone and nitrous oxide anaesthesia. When the incision in the cord has been made, the patient is allowed to wake and the level of analgesia is checked. Often successively deeper incisions are needed to secure a satisfactory high level. All perception of sharpness or disagreeable sensation on repeated pricking with a pin must be lost, a high degree of hypalgesia will not suffice.

A patient had severe pain in his legs as a result of chronic arachnoiditis of the cauda equina, for this he had undergone removal of an intervertebral disc, lysis of caudal adhesions, and two anterolateral cordotomies on each side under general anaesthesia, at the level of the 4th and 5th thoracic segments. Even in the sacral dermatomes analgesia was not complete. He was operated on under local anaesthesia, and four successively deeper cuts had to be made, at the level of the 1st thoracic vertebra, before analgesia could be raised to the level of the 12th thoracic segment. Fortunately it has remained at this level and he has been free of pain for two years.

In time the level of analgesia nearly always falls several segments occasionally to a much greater extent, and hypalgesia is substituted for analgesia. This process may pass unnoticed because without careful examination a high degree of hypalgesia is easily mistaken for analgesia. Even if the patient fails to recognise that single pricks or the scratches of a pin are sharp this does not prove that analgesia is complete. On facilitation, by rapidly repeated pricks, areas can often be found where this stimulus evokes a disagreeable response. When this has occurred, we have found a second deeper cordotomy effective in two thirds of the cases. Fall of the sensory level has been most common in the amputation stump neuralgias, particularly in those of the upper extremity where the spinothalamic tract has been divided at the level of the first cervical segment or in the medulla. On the other hand, as a result of faulty surgical technique the initial level of analgesia achieved may be insufficient and failures and disappointments may result.

It is fortunate that even the most extensive transections of the anterolateral quadrant produce relatively few complications (table 1). To our way of thinking, the risks of cordotomy are so slight in comparison to the psychic damage of leucotomy that we favour its trial, on one side at least, if there is any reasonable chance of success.

Cross-section of spinal cord at level of cordotomy at 2nd thoracic segment (Weigert, Pal, x 10). There was hypalgesia to xyphoid and analgesia to umbilicus. Relief of contralateral pelvic and leg pain from carcinoma of colon was complete. There was no bladder complication or leg weakness. The patient died of uraemia from ureteral compression. (This illustration demonstrates that even a very complete transection of the anterolateral quadrant may at times not result in a high level of analgesia.)

TABLE I—COMPLICATIONS OF CORDOTOMY (a) THOSE ARISING IN HOSPITAL AFTER 241 CORDOTOMIES ON 210 PATIENTS, (b) PERSISTENT COMPLICATIONS IN 20 PATIENTS EXAMINED 5 MONTHS TO 10 YEARS AFTER UNILATERAL CORDOTOMY

Type of cordotomy	No	Incidence of complications in hospital (%)				Deaths (%)
		Bladder	Bowel	Incision pain	Motor weakness

Vesical dysfunction	0	
Leg weakness	1	Slight at 20 mos
Ipsilateral decreased abdominal or cremasteric reflexes or increased tendon reflexes or Babinski's sign*	10	
Sexual dysfunction in males temporary absence of erection and orgasm postoperatively	3	Recovery in 5 mos to 2 yr
Root pain at level of incision	1	Stopped after 3 yr
Disagreeable paresthesias in anal gesio area	7	Severe in 1

* These patients had no troublesome spasticity

The results of cordotomy in malignant and non malignant disease are given in table II, which shows that relief of pain was satisfactory in 73–88% of the abdominal and pelvic malignancies, but was less complete in tumours of the breast, lungs, and bones where high spinal and thoracic metastases are so common. The relief in 71% of amputation stump neuralgias and painful conditions associated with disease of the spinal roots is comparable to that seen in the more favourable varieties of malignant disease.

It is a well-known experience with disease of the thorax, abdomen, or spine that a severe pain on one side may mask a slighter pain on the other. In these circumstances, after a unilateral cordotomy the patient soon begins to complain again of new discomfort on the opposite side. Among 89 cases of malignant disease of the torso cross over pain occurred early in 31, and after several months in 8 others. Pain became troublesome on the opposite side in 14% of patients with non-malignant disease of the torso, but never in those with lesions of the extremities. Failure of this sort after unilateral cordotomy is not of serious consequence, because it is easily corrected by an incision on the opposite side. Since a bilateral operation is often unnecessary, and because we have found that urinary complications are much less frequent if both anterior quadrants are not transected at a single stage, we prefer to start with a conservative unilateral cordotomy unless pain is severe on both sides.

Spinothalamic Tractotomy at Higher Levels—The spinothalamic tract was divided in the medulla oblongata by Schwartz (Schwartz and O'Leary 1941), and in a number of cases we have relieved neuralgia of the shoulder, neck, and pectoral regions by this procedure. The first of these remains free from pain after nine years (White 1941).

Spinothalamic tractotomy may also be undertaken in the mesencephalon, as was proposed by Walker (1942). At this level pain and temperature sensations are lost on the opposite side, both over the face and over the body. We have not been altogether satisfied with the results, for the operation carries an appreciably higher mortality and may lead to residual disagreeable sensations in the analgesic area.

SYMPATHECTOMY

Viscerosensory axones enter the spinal cord with the somatic sensory axones in the posterior roots. Their

second neurone crosses the spinal cord and ascends in the opposite anterolateral tract. The effective stimuli for visceral sensory nerves are dilatation of the vessel (Hurst 1911) and ischaemia of its wall (Sutton and Lueth 1930). These fibres are few in number considering their wide distribution, so that there is no overlapping of innervation whereby a small area is supplied by several fibres (Weddell et al 1948), and in consequence the threshold stimulus is high and the peripheral mechanism for localising the source of pain is poor. In these characteristics viscerosensory neurones resemble those subserving deep somatic structures such as ligaments and skeletal muscles (Lewis 1942).

Recent observations during operations under local anaesthesia have shown that direct stimulation of the inflamed appendix is perceived as painful (Kinsella 1948) and Bentley (1948) has shown that compression of a penetrating duodenal ulcer may cause distinct discomfort, which disappears after the splanchnic nerves have been blocked with procaine.

On several occasions during operations for hypertension, under nitrous oxide and local anaesthesia, we have allowed the patient to waken and have stimulated a major splanchnic nerve and the lumbar ganglia, this invariably produced deep abdominal pain. With the apparatus we employ, the voltage required is the same as that necessary to evoke a similarly intense response from the 12th intercostal nerve, and the latent period is roughly the same. Obviously then pain from a viscus can be abolished by dividing its sympathetic supply, either in its vascular pedicle or in the parent splanchnic trunks, by posterior rhizotomy, or by anterolateral cordotomy. Clinical experience has shown that interruption of sympathetic nerves is nearly always successful in relieving pain of purely visceral origin (table III).

Angina Pectoris—The results of surgical interruption of the cardiac pain fibres which pass through the upper three or

TABLE II—RESULTS OF CORDOTOMY FOR RELIEF OF PAIN IN MALIGNANT AND NON MALIGNANT DISEASE

Malignant					
Site of growth	No of cases	Good relief	Spread to other levels	Inadequate level	Operative deaths

	Presacral neurectomy with suspension &c.	72	4	13	—

four thoracic sympathetic ganglia and the corresponding posterior spinal roots have been reviewed elsewhere (White and Bland 1948). Patients have been submitted to surgical procedures only when medical treatment has failed to control frequently recurring bouts of severe pain. In these circumstances, effective chemical interruption of the pain pathways has been successful in 49 cases, with reduction of the severity of the attacks to a point where they can be fairly well controlled by nitrites in 16 others. There were 6 failures from incomplete block and 7 deaths in hospital, mostly from coronary thrombosis. Intercoastal neuralgia was a troublesome postoperative complication in 10%, but always subsided within three months. All the cases treated by upper thoracic sympathetic ganglionectomy were relieved of pain referred to the precordium and arm on the denervated side. The same has been true of posterior root section in our single experience, and in 30 other cases from various clinics in the United States (see White and Bland 1948). The mortality rate in the surgically treated cases has been only slightly higher than in those denervated by chemical block. On this account, and because of the greater certainty of relief, we are treating an increasing proportion by ganglionectomy, or, if the pain is bilateral and the patient a favourable risk for operation, by section of the posterior roots. Many of these patients have now been followed for periods of from two to eleven years. There have been few recurrences of angina and all the patients have preserved adequate but painless warnings of their attacks.

Aneurysms of Aortic Arch—Three cases with severe pain relieved by paravertebral injection of the upper thoracic ganglia with procaine and alcohol were reported by White (1932). In the past year a woman with two aneurysms in the descending arch and upper thoracic portion of the aorta has been freed of very intense pain by cutting the upper seven thoracic posterior roots on the left side in two stages.

Liver and Biliary Tract—Carcinomatous metastases to the liver are rarely painful but in a single case with rapid distension of the hepatic capsule from mammary cancer injection of the splanchnic rami resulted in complete relief for the last weeks of life. This woman was particularly grateful because she had been unable to tolerate morphine in any form.

Pain may also persist after multiple operations on the biliary ducts. In cases where there is no other solution pain of this sort may be relieved by right-sided splanchnicectomy (White and Smithwick 1941).

Pancreatic Calculi and Fibrosis—Distension of the pancreatic ducts may produce severe epigastric pain with radiation to the back. Mallet-Guy and de Beaulieu (1947) were the first to show that this can be relieved by splanchnicectomy. We

have had two successful results in patients with inoperable disease of the pancreas and failure in a third after pneumonia and a series of unfortunate postoperative complications.

Duodenal Ulcer—Although there is ordinarily no justifiable reason for treating cases of duodenal ulcer by sensory denervation, we have seen 2 patients with severe epigastric pain secondary to penetrating lesions in whom direct surgical intervention was considered inadvisable on account of advanced coronary disease. Smithwick (White and Smithwick 1941) was able to relieve their pain by alcohol injection of the right splanchnic rami.

Intestinal Dyskinesia—Sarnoff et al. (1948) have applied this term to a syndrome consisting of painful bouts of intestinal distension in which no definite obstructive lesion can be found, even at repeated laparotomies. In 5 cases temporary relief after passage of flatus followed differential spinal block with procaine in 4 of these the attacks were permanently stopped by splanchnicectomy.

Nephralgia—Pain which clinically resembles renal colic and can be reproduced by distension of the kidney pelvis may occur without any definite urological lesion. The effectiveness of denervating the renal pedicle has been established by Oldham (1936), and in our hands in 3 cases. The case listed as a failure in table III was relieved of his original pain, but has reported pain at a higher level which we have not had an opportunity to investigate.

Dysmenorrhœa—Resection of the superior hypogastric plexus (so-called presacral neurectomy) gives relief in a large proportion of cases of idiopathic dysmenorrhœa. At the Massachusetts General Hospital, Ingersoll and Meigs (1948) have reported excellent results in 87 cases, improvement in 7, and failure in 16. Resection of the presacral plexus alone is capable of giving almost as good results as when it is combined with supplementary suspension of the uterus, plastic procedures on the tubes and cervix, &c. These writers give an interesting analysis of the causes of failure.

I want to emphasise that the effectiveness of sympathectomy is limited to pain originating in the heart, aorta, and abdominal viscera. It will not relieve pain originating in the œsophagus, bladder, prostate, or cervix uteri, where the majority of afferent fibres run in the vagi or sacral nerves. Also, sympathectomy cannot be expected to relieve pain in malignant disease of the viscera, since this does not usually develop until the lesion has burst through the capsule of the organ and invaded structures in the parietal pleura and peritoneum which are supplied by spinal nerves.

In addition to its importance in the control of visceral pain, sympathectomy is of great value in the relief of causalgia and the post-traumatic dystrophies. In these conditions the beneficial result seems to be related to improvement in circulation, and it is doubtful if any pain pathways are interrupted.

Causalgia—The relief by sympathectomy of burning hyperæsthesia in typical war time cases of causalgia has been most gratifying. White et al. (1948) summarised the cases reported during the war and added 13 from a United States Naval Hospital. All the latter had immediate temporary improvement of their pain after paravertebral procaine block and lasting relief following sympathectomy.

Post-traumatic Arthritis—In a series of cases of post-traumatic arthritis of the extremities equally striking benefit was obtained. These patients had suffered contusion of the joints with actual fractures in 4 cases, and the ensuing painful osteoporosis appeared to be related to local impairment in circulation. In 3 of them satisfactory relief was obtained from procaine block alone, repeated on one or more occasions. The other 4 ultimately required sympathectomy and were then able to start physiotherapy and active use of their decalcified and atrophied extremities.

Amputation Neuralgia—Although we have never been able to influence pain after major amputations, excellent results followed paravertebral block and subsequent sympathectomy in 3 cases of amputated fingers and toes, where the pain was accompanied by vasoconstriction, cyanosis, and hyperhidrosis.

Sympathectomy is a safe and harmless procedure after which the patient notices only a regional vaso-dilatation and loss of sweating. Granted that the cases are selected and tested with care, the results have been most gratifying. I realise that this may seem a

TABLE IV—RESULTS OF UNILATERAL LEUCOTOMY FOR PAIN

Cause of pain	Relief			Duration
	Good	Fair	Poor	
Carcinoma of face and neck	3	3	—	2 weeks to 7 mos
Multiple bony metastases	—	1	1*	3 and 15 mos
Thalamic syndrome	—	1*	—	8 mos

Post sympathectomy	—	1	—	—
Arachnoiditis	—	2	—	2 and 8 mos

* These patients at first had good results but after six months their pain returned partially or completely

dogmatic statement, but from personal experience I am sure that I can relieve these types of pain with greater certainty than many of the somatic neuralgias

PREFRONTAL LEUCOTOMY

I hope that I have made clear what specific somatic and visceral denervation can accomplish within the limitations of present day knowledge. While failures most often follow errors in surgical technique or incomplete knowledge of anatomy, the selection of patients for operation may also be at fault, so that drug addicts and psychoneurotics have been included. To improve his batting average, the neurosurgeon needs the cooperation of the referring practitioner and often of the psychiatrist. Operations for relief of pain must be undertaken before the onset of drug addiction. The psychiatrist must weed out the cases of compensation neurosis and functional pain.

Frontal leucotomy is being too often advocated as a simple solution of the relief of suffering—for example, in tabetic crises, in pelvic carcinoma, and even in causalgia. In view of the psychological deterioration which ensues when the frontothalamic connections are cut on both sides, there is no justification for recommending this operation for the relief of conditions that can be taken care of by an adequate cordotomy, rhizotomy, or sympathectomy. As I see it, leucotomy is an admission of failure, and it should be undertaken only when other measures are already known to be ineffectual, or after they have been tried unsuccessfully.

After bilateral prefrontal leucotomy for pain, it has seemed to us that our patients have been more upset psychologically than those operated on for schizophrenia or other psychiatric conditions. Le Beau's (1950) preliminary report on bilateral topectomy, which he has carried out in 25 cases for relief of persistent pain, indicates that this operation may cause a much lesser degree of mental deterioration. As yet we have had too limited an experience with topectomy to have come to any opinion. We have, however, tried two modifications of leucotomy.

Bilateral transection limited to the lower quadrants of the frontal lobes has left the patients in a peculiar apathetic state. Unilateral extremely complete transection of one frontal lobe, as advocated by Scarff (1949), has given fairly promising results in 11 of 13 trials (table iv). If these patients have remained alive for but a short time, their suffering has been greatly relieved, but in 3 of the 5 who survived for over six months pain has recurred to a troublesome extent. In the case with atypical facial neuralgia a secondary leucotomy of the opposite frontal lobe was subsequently carried out, this has resulted in great improvement with minimal psychological deterioration. The patient with the thalamic syndrome may likewise require a second leucotomy. Contrary to Scarff's observation that there is no demonstrable psychical change after a unilateral operation, Cobb and Bonner (to be published) of our psychiatric staff have often found quite definite changes

Fortunately these have been neither lasting nor serious. As there is no contra indication to carrying out frontal leucotomies in stages, my colleagues and I favour unilateral complete transection of the frontal white matter in all cases where the operation is done for pain. If pain returns or is inadequately relieved, a second section on the opposite side can be carried out later. In these circumstances early experience in our hands and reports from other clinics seem to indicate that pain is relieved as effectively and with less psychical deterioration than after the one stage bilateral operation.

CONCLUSION

It is obvious that we are still somewhat short of our goal of controlling all varieties of pain by neurosurgical intervention. We have as yet no certain method for the specific interruption of the pain pathways in some of the postamputation phantoms, especially in the upper limb, for pain following injuries of the spinal cord (as distinguished from the cauda equina), or for the burning hyperæsthesia of the thalamic syndrome. Furthermore, even our most trusted operative procedures may fail: cordotomy by late falls in analgesic level, and sympathectomy by regeneration of visceral afferent neurones. To solve these particular problems, animal experimentation is of little value, we must rely more on direct observations on the conscious human patient. Here only the scientific curiosity and physiological ability of surgeons can advance our knowledge.

PURPURA IN PREGNANCY

WITH SPECIAL REFERENCE TO IDIOPATHIC THROMBOCYTOPENIC PURPURA

H N ROBSON

L S P DAVIDSON

B A. Camb, M.D. Edin., F.R.C.P., F.R.C.P.E., F.R.S.E.
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF EDINBURGH

As a complication of pregnancy purpura is rare and regarded as of grave import. "Purpura" denotes hæmorrhage from skin and mucosæ due to a bleeding tendency. The causes of such a bleeding diathesis are many and may be classified as follows

- (1) *Thrombocytopenic purpura*
 - (a) Idiopathic thrombocytopenic purpura
 - (b) Symptomatic thrombocytopenic purpura
- Blood diseases—e.g. leukaemia, aplastic anaemia, and pernicious anaemia
Toxic agents—e.g. heavy metals, quinine, ergot, sulphonamides, X rays, radium and severe burns.
Systemic diseases—e.g. severe infections, septicæmia, uræmia, eclampsia and carcinomatosis
Splenic disorders—e.g. congestive splenomegaly, reticulosis, tuberculosis, kala-azar

(2) *Non-thrombocytopenic purpura*

(a) Associated with vascular defect

Anaphylactic—e.g., Schönlein's purpura and Henoch's purpura

Toxic and symptomatic—e.g., chemicals and drugs, infections and systemic diseases

Avitaminosis—e.g., scurvy

(b) Associated with coagulation defect

Hypoprothrombinæmia and fibrinogenopenia

(c) Hereditary defect

Telangiectasia and "thrombasthenia"

It will therefore readily be appreciated that purpura in pregnancy may be due to one of many different causes. Rushmore (1925) collected from the literature 47 cases and added 1 of his own. These cases included instances of purpura arising from such diverse conditions as rheumatic fever, septicæmia, eclampsia, smallpox, and scurvy. The over-all mortality rate in this heterogeneous collection was given as 26 maternal deaths out of 44 (59.1%), and 27 infant deaths out of 42 (64.3%). Later workers (deSaussure and Townsend 1935, Polowe 1944, Patterson 1946, and Chalmers 1948) have continued to quote Rushmore's figures, and have implied that these mortality rates are applicable to one particular type of purpura in pregnancy—e.g., idiopathic thrombocytopenic purpura. In discussing this latter condition as a complication of pregnancy, Wintrobe (1946) and Whitby and Britton (1946) in their textbooks give mortality-rates based on Rushmore's original figures.

The prognosis in any given case of purpura in pregnancy must surely depend to a great extent on the type and cause of the purpura, and we intend here to show that these widely quoted mortality-rates are not universally applicable, and that they certainly do not hold good, for example, when idiopathic thrombocytopenic purpura is associated with pregnancy.

Since Rushmore (1925) reviewed 48 cases of purpura in pregnancy, some 47 further examples have been reported. We have studied these 95 cases in an attempt to classify them, if possible, and to determine the particular type of purpura present. In addition, a further 4 cases of idiopathic thrombocytopenic purpura associated with pregnancy are reported.

IDIOPATHIC THROMBOCYTOPENIC PURPURA AND PREGNANCY

It is generally agreed that, to sustain a diagnosis of idiopathic thrombocytopenic purpura, the following criteria must be fulfilled. There must be no history of exposure to toxic agents, or sensitivity to drugs, and there must be no history or signs of other diseases likely to cause thrombocytopenia. The cardinal hæmatological features are thrombocytopenia, prolongation of the bleeding time with a normal clotting time, increased capillary fragility, and normal or increased numbers of megakaryocytes in the bone marrow.

Of the 95 cases of purpura in pregnancy which have now been reported 21 have been identified as examples of idiopathic thrombocytopenic purpura, and these are shown in table I, together with the 4 further examples reported here. These 25 reports provide records of 4 pregnancies, in which bleeding was present during the course of gestation in 24 instances. There were 2 maternal deaths (mortality 5.9%), one as a result of abortion and cerebral hæmorrhage, and the other from intracranial hæmorrhage. Among the 32 viable babies there were 2 stillbirths and 6 neonatal deaths (mortality 5.0%). 18 of the babies showed purpura with thrombocytopenia at or shortly after birth, and of the 3 deaths 4 were apparently due to hæmorrhagic disease. As regards parity, the purpura was noted in primigravida in 17 cases, during the second pregnancy in 4, in the fourth in 2, and in the sixth in 2. In 4 of the patients adequate clinical and hæmatological

data were available to indicate that idiopathic thrombocytopenic purpura had been present before pregnancy. In 6 cases no such evidence was available, and the condition appeared for the first time during pregnancy. Of the remaining 8 patients 7 gave a definite history of previous purpuric episodes, and 1 had noted a tendency to excessive bruising. Although no hæmatological data are available in these 8 cases, it seems likely that idiopathic thrombocytopenic purpura had been present before pregnancy. Of those 19 patients known to have the disease, or giving a suggestive previous history, signs were present from the beginning of pregnancy in 7 cases, and in another 6 cases purpura appeared at the fifth month. In the 6 cases in which the disease appeared for the first time in pregnancy the time of onset ranged from the third to the eighth month. Blood loss at delivery was recorded as normal in 25 cases and excessive in 4. Only 1 of these latter 4 patients received a blood-transfusion shortly before or during labour. On the other hand, 9 of the 25 cases with normal blood loss were given blood transfusions near the time of delivery. Conservative treatment was adopted in 17 cases, with 2 maternal deaths, both taking place in the early months of pregnancy. The remaining 15 mothers were safely delivered at term. 2 infants died in this group, one stillborn and showing purpura, and the other on the fourth day without purpura.

Splenectomy was done during the course of pregnancy in 2 cases. In one (Bernstein et al 1939) the operation was successfully performed at the fifth month, but premature labour ensued two months before term, and the child, which was not purpuric, survived only eight days. In the second case (Phythyon and Lartz 1943) splenectomy was done a month before term, successfully as regards the mother, who, however, went into premature labour two days later and was delivered of a stillborn non-purpuric child.

In 8 women 15 pregnancies occurred at various intervals after splenectomy for idiopathic thrombocytopenic purpura, and in these pregnancies there were no maternal deaths. In 7 of these instances the mother had thrombocytopenia and recurrence of purpura during pregnancy, 6 of the infants showed purpura, and 3 of these babies died from hæmorrhagic disease. In the other 8 instances the mothers had no purpura during pregnancy, but 3 of their infants were purpuric at birth. None of the infants died from bleeding in this group, the single neonatal death being due to atelectasis and prematurity.

OTHER TYPES OF PURPURA AND PREGNANCY

The classification given earlier indicates the numerous causes of symptomatic thrombocytopenic purpura and of non-thrombocytopenic purpura. It should be noted that certain infections, toxic agents, and systemic diseases can produce purpura in which the platelet-count may be either normal or reduced. In the best of circumstances, therefore, classification may be difficult. Cases of purpura in pregnancy reported since Rushmore's (1925) review which do not satisfy the criteria for a diagnosis of idiopathic thrombocytopenic purpura are shown in table II, with an indication of the probable cause of the purpura. To these has been added an illustrative selection of some of the earlier cases included in Rushmore's paper. The cases in table II are arranged in the order of the classification of the causes of purpura used here. There seems to be little justification for any attempt to draw conclusions about mortality or prognosis in such cases. Purpura and thrombocytopenia in these are but incidental manifestations of the underlying disorder, and the outcome in any given case must depend on the nature and the severity of the causal disease. Certain points may, however, be noted. The appearance of purpura in the infants of mothers with symptomatic thrombocytopenia is illustrated in the cases

reported by Posner (1937), Leschke and Wittkower (1926), Landolt (1948), Guggsberg (1936), and Goldstein (1947). The failure of splenectomy as a therapeutic measure in conditions in which the spleen is not concerned with the production of thrombocytopenia is shown by the case records of Hottenstein and Klingman (1927) and Boley (1930). On the other hand, the interesting report of Polowe (1944) gives details of successful splenectomy in a case of what might now be termed "secondary hypersplenism."

CASE RECORDS

In recent years 4 examples of idiopathic thrombocytopenic purpura associated with pregnancy have been encountered by us. In 2 the disease was proved to have

been present before pregnancy, whereas in the other 2 cases a history of a bleeding tendency suggested a pre-existent thrombocytopenic state, although haematological data were not available.

Case 1—A 3 para, aged 35, was admitted to hospital April 11, 1947, as having had an incomplete abortion at the fourteenth week. Previous pregnancies were reported as normal. The patient stated that she had always bled easily, had had occasional epistaxis, and had noted a skin rash once. Her periods before pregnancy had been regular but not heavy. There was no history of drug taking or exposure to toxic agents. At the second month of the present pregnancy there had been a severe epistaxis and slight vaginal bleeding, which had recurred later at the third month and continued until admission.

On examination petechiae were seen on the abdomen and face, the gums were bleeding, and there were ecchymoses

Cases reported by Adair (1925), Bayer (1931), Tessauro (1932), and deSaussure and Townsend (1935) were probably idiopathic thrombocytopenic purpura but the data given are not adequate. The examples recorded by Dinsmore and Dutilleul (1946) and Nordland et al. (1946) have not been traced.

TABLE II—CASES OF OTHER TYPES OF PURPURA AND PREGNANCY

Reference	Mother				Child		Remarks

The cases reported by Palombelli (1932) and Henriët (1933) have not been studied

on the legs. The spleen was impalpable. There was no pyrexia. No other abnormality was found on clinical examination. The uterus was evacuated shortly after admission, with resultant profuse hemorrhage.

Next day, the blood findings were Hb 40%, red cells 2,400,000 per c.m.m., white cells 12,000 per c.m.m., platelets 15,000 per c.m.m., and blood ascorbic acid 0.28 mg per 100 ml. The bleeding time exceeded 10 min., and the Hess test was strongly positive. 2 pints of blood was transfused.

On April 13 when the patient appeared to be improving, she suddenly developed headache, lost consciousness, and died that evening.

Necropsy showed no evidence of uterine infection or systemic disease other than widespread hemorrhages in many organs including the brain. The spleen was slightly enlarged, and the bone-marrow was active, with plentiful megakaryocytes.

Case 2—A primigravida aged 25, was admitted to hospital on April 1 1946 at the 36th week of pregnancy, with epistaxis and petechial and ecchymotic skin hemorrhage. There was no family history of bleeding, and the patient had had no illness of note until she had begun to have bronchial asthma at the age of 14. At the age of 23, when she was a member of the A.T.S. she had begun to bruise spontaneously. She had been admitted to the Royal Infirmary, Aberdeen, where idiopathic thrombocytopenic purpura had been diagnosed. She had continued thereafter to have intermittent bleeding episodes. The present pregnancy had been uneventful for the first six months but from the sixth month there had been frequent epistaxes, petechial rashes and ecchymoses.

On examination petechiae were seen on the abdomen and bruises on the legs. There was no clinical evidence of other systemic disease. The blood findings were Hb 76%, red cells 4,160,000 per c.m.m., reticulocytes 3%, and platelets 0.000 per c.m.m. The bleeding time was 20 min. and the clotting time 6 min. clot retraction was poor and the capillary resistance (negative-pressure method) was less than 200 mm Hg. Sternal puncture revealed an active normoblastic marrow with increased numbers of megakaryocytes.

The patient was thereafter observed in hospital. The platelet count ranged from 10,000 to 30,000 per c.m.m., and the bleeding time from 12 to 30 min. Epistaxes were frequent. Transfusions of blood were given at intervals, and one was given the day before the patient went into labour at term on April 31. She was delivered spontaneously, without excessive blood loss, of a normal male child. The child showed no purpura, his platelet-count (indirect method) on the second day was 210,000 per c.m.m., and he has since thrived.

The mother's puerperium progressed normally until the 14th day when purpura reappeared. Thereafter she continued to have intermittent purpuric episodes and menorrhagia until October, 1947, when splenectomy was done in Bristol Royal Infirmary. This led to a complete clinical remission up to the end of 1948, when the patient was last seen although the platelet-count had then fallen to 55,000 per c.m.m. from a postoperative peak of 517,000 per c.m.m.

Case 3—A primigravida aged 20, was admitted to hospital on July 18, 1949 seven months pregnant, with petechial rash, epistaxis, and bleeding from the gums. She stated that she had always bruised easily and bled excessively from cuts. At the age of 15 she had had a profuse vaginal hemorrhage. Her periods normally were regular and the loss moderate. At the third month of the present pregnancy she had had epistaxis. Three weeks before admission bleeding from the gums had been noted followed shortly by petechial rashes on the skin, and then the epistaxis had recurred. There was no history of having taken drugs or of having been exposed to toxic agents.

On examination petechiae and ecchymoses were seen, the gums were bleeding and there was microscopic hamaturia. Physical examination revealed no other abnormality, and the obstetric findings were those of a normal pregnancy about the 30th week. The blood findings were Hb 69%, red cells 3,980,000 per c.m.m., white cells 12,000 per c.m.m., and platelets 25,000 per c.m.m. The bleeding time was 10 min., and the clotting time 5 min. the capillary resistance to negative pressure was less than 200 mm Hg. The sternal marrow showed normoblastic erythropoiesis and abundant megakaryocytes.

The patient remained in hospital under observation, and the remainder of pregnancy was obstetrically normal but punctuated by episodes of bleeding. Transfusions of blood were given at intervals. The platelet-count ranged from 30,000 to 80,000 per c mm, and at delivery was 25,000 per c mm. Labour began at term and was completed spontaneously on Sept 27, with very slight blood loss. Blood was transfused slowly during and after labour. The infant was male and weighed 7 lb 10 oz at birth, a few purpuric spots were seen on his body twelve hours after birth, when the platelet count was 130,000 per c mm. These spots faded quickly and no further bleeding took place. On the second day of his life his Hb was 160% and platelets 85,000 per c mm. On the 14th day the platelets had fallen to 30,000 per c mm, but by the 21st day these had risen again to 125,000 per c mm. On the 72nd day the platelet-count was 370,000 per c mm. The child thrived normally, but was weaned from the breast on the tenth day.

The mother began to have abnormal vaginal bleeding on the 5th day of the puerperium, when her platelet-count was 60,000 per c mm, about which level it remained. Vaginal bleeding continued, and petechiae, epistaxis, and bleeding from the gums recurred. Since no evidence of remission was forthcoming, splenectomy was done on Nov 3. The response to operation was disappointing because, although clinical remission followed and was maintained for the next five weeks, the platelet-count on discharge from hospital on Dec 8 was still only 60,000 per c mm.

This is the second case only of a series of 24 cases of idiopathic thrombocytopenic purpura studied by us in which the response to splenectomy has been so poor.

Case 4—The patient had been admitted to the Royal Infirmary, Aberdeen in 1937, at the age of 26, with a year's history of petechial rashes, ecchymoses, and menorrhagia. There was no family history of a bleeding tendency, and the patient's previous history had been uneventful. No cause of symptomatic purpura had been found, and idiopathic thrombocytopenic purpura had been diagnosed. The blood findings at that time had been Hb 56%, red cells 3,900,000 per c mm, and platelets 20,000 per c mm. Splenectomy had been done. Since then the patient had been in good health and no further bleeding episodes had occurred. In 1946 the patient had become pregnant for the first time, and developed signs of severe toxæmia at the sixth month. Caesarean section was done five weeks before term. The platelet-count at this time had been 365,000 per c mm, the bleeding time 2 min, and the capillary resistance normal. The patient had made a good recovery without incident, but the infant had survived only 36 hours. Necropsy had shown atelectasis of the lungs but no evidence of hæmorrhagic disease. In 1948 the patient again became pregnant, all blood findings still being within normal limits. Pregnancy was uneventful, and a normal healthy child was delivered by caesarean section at term. Both mother and child have since remained in good health.

DISCUSSION

The fallacy of conclusions based on cases of many different forms of purpura in pregnancy was pointed out by Burnett and Klass (1943), who presented a classification of 22 cases of all types, of which they identified 4 as being idiopathic thrombocytopenic purpura, and added a fifth personal case. A group of 5 cases is too small, however, to provide much information. By a study of the 25 cases of idiopathic thrombocytopenic purpura shown in table 1 it is now possible to draw conclusions of some value.

It seems unlikely that pregnancy is a factor in the production of idiopathic thrombocytopenic purpura. This disease is known to affect mainly females below the age of 30 (Wintrobe et al. 1937). Since this age coincides with the maximal incidence of pregnancy, a study of the age incidence of the two conditions combined is not likely to be informative. The disease became manifest for the first time during pregnancy in only 6 of the total of 25 cases, and in these 6 cases the time of onset varied widely from the third to the eighth month. These findings, together with the great rarity of the combination of pregnancy and idiopathic thrombocyto-

penic purpura, suggest that the association is accidental. There is no real evidence in the present study to suggest that pregnancy precipitates or aggravates the manifestations of the disease. Although 17 of the 25 patients showed signs of the disease during the first pregnancy, most of these primigravidae had had bleeding episodes before, and were known or suspected to have had the disease before pregnancy. The maternal mortality in these 25 cases, involving 34 pregnancies, was 2 (8%), which is no greater than the expected mortality of the disease in the non pregnant (Wintrobe et al. 1937). The infant mortality was high (25%), but even this figure is much less than that quoted by some workers (deSaussure and Townsend 1935, Chalmers 1948). It is interesting that both maternal deaths took place in the early months of pregnancy and not, as might be expected, at the time of childbirth. Indeed, the remarkable feature emerges from this study that delivery can and usually does take place without excessive blood loss. In 25 of the 34 pregnancies the blood loss associated with delivery was recorded as being within normal limits, even though many of these patients were profoundly thrombocytopenic at the time. Though blood transfusion may well be a factor in preventing or relieving hæmorrhage at delivery, it must be noted that only 9 of the 25 deliveries in which blood loss was normal were preceded or accompanied by blood transfusion. Perhaps this remarkable freedom from hæmorrhage at and shortly after delivery is due to some mechanism similar to the increase in capillary strength which has been shown to develop during and after surgical operations (Robson 1949). In case 2, on the second day of the puerperium, the capillary resistance was very high and the bleeding time short. The recurrence of bleeding later in the puerperium, which is reported in many of the cases, might also support the suggestion that some protective mechanism operates temporarily during labour and delivery.

The appearance of thrombocytopenia and purpura in the infant is strikingly illustrated in this series, occurring in 18 out of 32 cases, and was the cause of death in 4 infants. The usual course of events in the newborn seems to be the appearance of purpura within a few hours of birth, persisting for some days, and then recovering spontaneously. Three examples are well described by Talmadge and Berman (1947). The findings suggest the transmission of some circulating factor from mother to child, and it was because of this possibility that the child of case 3 was taken from the breast on the tenth day. On the other hand, Patterson (1946) reports spontaneous recovery in a purpuric child who was breast fed throughout.

As regards treatment in cases of pregnancy associated with idiopathic thrombocytopenic purpura, the number of cases allows only tentative conclusions to be drawn. In 17 cases treated conservatively there were 2 maternal deaths (11.8%). Of the 15 viable babies 9 showed purpura, and 1 of these purpuric infants was stillborn. Splenectomy for idiopathic thrombocytopenic purpura had been done at various intervals before pregnancy in 8 patients. 5 of these had recurrence of purpura at thrombocytopenia, and in the ensuing 9 pregnancies there were no maternal deaths, but 8 of the 9 babies were purpuric, and 3 of them died from hæmorrhage. The remaining 3 patients who had undergone splenectomy had no recurrence of purpura, in the 6 pregnancies which followed there were no maternal deaths, only 1 of the 6 babies showed purpura, and none died from hæmorrhagic disease. It therefore seems that purpura and death are more likely to occur in babies whose mothers have undergone splenectomy with subsequent recurrence of purpura than in infants whose mothers have either not required splenectomy or have not relapsed after the operation. These findings suggest that, when the

adency to thrombocytopenia and hemorrhage is so strong in the mother that splenectomy does not control the infant is subjected to a similar powerful influence, with a corresponding risk of bleeding. Only two examples of splenectomy for idiopathic thrombocytopenic purpura during pregnancy have been found, and both the infant died, although both mothers survived. Immediate danger to the mother's life seems to be the principal indication for splenectomy during pregnancy.

The cases of symptomatic purpura (table II) are too limited to allow any general conclusions to be drawn. The table illustrates some of the many possible causes of purpura in pregnancy and indicates the necessity for accurate classification before drawing conclusions about any one particular type. The occurrence of purpura in the infant is interesting and suggests again, perhaps, a transplacental passage of some factor causing thrombocytopenia in the child. The case reported by Howle (1944) shows that splenectomy can be done in pregnancy as late as the eighth month without harm to the child.

SUMMARY

Of the 95 cases of purpura in pregnancy that have been published, 21 have been identified as examples of idiopathic thrombocytopenic purpura, and 4 further cases of this condition complicating pregnancy are reported.

In these 25 cases the maternal mortality was less than 10%, and the infant mortality about 25%. Previous conclusions about mortality have been misleading, being based on an unclassified series of cases of purpura of many different types.

There is no satisfactory evidence that the association of idiopathic thrombocytopenic purpura and pregnancy is more than accidental, or that pregnancy significantly influences the course of the disease.

The recorded deaths occurred in the early months of pregnancy.

Bleeding at delivery was rarely excessive.

Thrombocytopenia and purpura in the infant was frequent but usually transient.

These manifestations developed more often, and tended to be more severe, in infants whose mothers had not responded clinically and haematologically to splenectomy.

We wish to thank Prof R J Kellar and Prof R B Ellis, of the University of Edinburgh, and Prof C B Perry, of Bristol University, for their kind co-operation in supplying information for the case records.

SALICYLATES IN ACUTE OSTEOMYELITIS

P G KONSTAM

FRCS.E

ACTING DIRECTOR,

CLINICAL PATHOLOGIST

ALTHOUGH interest has lately been focused on the effect of salicylic acid and its derivatives on the metabolism of Koch's bacillus, and *p*-aminosalicylic acid has been introduced into the therapy of tuberculosis, little has so far been published on the effect of salicylic acid on the pyogenic organisms. In the only paper on this subject which we have found, Ivanovics (1942) states that sodium salicylate has a bacteriostatic effect on *Staphylococcus aureus*. He describes two mechanisms: one is a "specific antiseptic action," and the other a direct toxic action on bacterial protein by a process of denaturation. The specific action is inhibited by small amounts of pantothenic acid, and the only salicylic acid derivatives which have this action are acetylsalicylate and salicylic acid phenyl esters.

We describe here an unusual effect obtained by the administration of large doses of sodium salicylate or aspirin to patients with acute osteomyelitis who responded poorly to penicillin. These cases may be of interest in view of the growing number of penicillin resistant strains of *Staph aureus*.

In 1945 a middle aged woman was admitted to hospital with severe burns of trunk and extremities. The lesions became infected with *Staph aureus* despite penicillin therapy. Subsequently the patient developed a pericardial effusion. The house surgeon, considering this to be of rheumatic origin, put the patient on large doses of salicylates. The pericarditis cleared rapidly and the burns very quickly healed, the patient making a rapid recovery. Since the "rheumatic" origin of the heart lesion seemed unlikely, it was thought that there might have been a synergistic effect of penicillin and salicylate on penicillin resistant staphylococci. There happened to be a patient in the ward at the time with severe subacute osteomyelitis of the upper humerus which was not responding to penicillin. As soon as he had been given a day's course of sodium salicylate gr 30 three hourly, his temperature fell to normal and his condition improved dramatically.

In spring, 1949, the opportunity arose to treat four further cases of proved acute osteomyelitis in the manner described.

CASE-RECORDS

Case 1—A boy aged 13 was admitted to hospital on April 11, 1949, with five days' history of throbbing, swollen, and

aching right knee. He was flushed, with temperature 101.4°F, and pulse rate 115. There was much tenderness over both condyles of the femur, the skin was oedematous. There was no obvious effusion into the knee joint, and the knee could be flexed to 90° without causing much pain.

Acute osteomyelitis of the lower end of the femur was diagnosed, and the patient was given penicillin 100,000 units three hourly. By April 13 the tenderness over the femoral condyles had almost disappeared, but pyrexia persisted. Sulphadimidine was added to the penicillin without effect on the pyrexia. On April 18 calcium aspirin gr 10 four hourly was ordered, and the temperature settled within twenty-four hours (fig. 1) and remained normal thereafter. Convalescence was uneventful.

Radiography at the end of the second week of illness showed osteomyelitis of the lower third of femur. No pus was obtained for culture.

Case 2—A boy, aged 13, was admitted on May 2, 1949, having a week earlier received a knock against the left knee and leg. The upper part of the leg had gradually become swollen and painful. The child could neither stand on it nor move it. A "sore" had broken out on the right arm two days before admission.

He was flushed, wide awake, with temperature 102°F, and pulse rate 110. "Cellulitis" was present over the upper part of the left tibia, which was extremely tender. There

Fig. 1—Temperature chart of case 1.

was no clinical evidence that the knee joint was involved. There was superficial dirty ulceration over the dorsal border of the right ulna (7 metastatic abscess).

The leg was immobilised on a Thomas splint, and penicillin 200,000 units three hourly was given. On May 4 fluctuation was present over the subcutaneous border of the tibia, and an extensive subperiosteal abscess was explored and drained. Pus was oozing from one point in the bone. Here the bone was drilled and a shallow gutter was made. The wound was left open and soft paraffin gauze inserted. A plaster of Paris cast was applied. On May 5 the child was put on calcium aspirin gr 10 four hourly. The temperature fell to normal within twenty-four hours (fig. 2), and convalescence was uneventful.

A pure growth of coagulase positive *Staph. aureus* was obtained which was penicillin resistant on a plate sensitivity test.

Case 3—A girl, aged 15, was admitted on March 9, 1949. Nine days earlier she had returned from school complaining of pain in the right thigh. When seen by her doctor her temperature was 102°F, and she looked ill and complained of tenderness and pain over the right thigh, just below the inguinal ligament. The pain kept her awake at night.

Her temperature was 101.4°F, and pulse rate 104. The skin around the right hip joint was hot and tender, and there was swelling about the joint. All movements were very painful. The joint was aspirated and 5 ml. of turbid yellow fluid was withdrawn. The exudate showed masses of pus

Fig. 2—Temperature chart of case 2.

cells. No tubercle bacilli were found, and none grew in culture.

The limb was immobilised on a Boehler Braun frame with traction. Penicillin 100,000 units three hourly and sulphathiazole 2 g immediately and 1 g three-hourly were ordered. Pyrexia persisted for twenty-one days, so the patient was given calcium aspirin gr 10 four hourly. Her pyrexia settled within twenty-four hours (fig. 3), and clinical improvement continued without interruption.

A series of X-ray films, showing at first decalcification of the right femoral neck, finally established the diagnosis of osteomyelitis of the upper third of the femur.

Case 4—A man, aged 22, was admitted on April 7, 1949. Six weeks previously he had sprained his left wrist. Five weeks later he had felt ill, and shortly afterwards experienced severe throbbing pain at first in the left wrist and later spreading up the left arm. Symptoms had increased until admission to hospital.

The temperature was 100°F, and the pulse rate 80. The left forearm, the wrist, and the back of the hand were swollen and tender. The main tenderness was over the lower end of the ulna. There was some enlarged non-tender glands in the axilla.

Acute osteomyelitis of the left ulna was diagnosed. An incision over the ulna liberated a large quantity of pus. The periosteum was found raised from the bone, and pus was found underneath it. Five holes were drilled into the distal end of the ulna, and pus escaped from them. The wound was left open, and a soft-paraffin gauze pack was inserted. The limb was put to rest in plaster slabs. Penicillin 200,000 units and sulphadimidine 2 g followed by 1 g four hourly were ordered (fig. 4).

The patient's general and local condition was satisfactory, and penicillin treatment was continued until April 22, when his temperature began to rise again. On April 25 he presented

Fig. 3—Temperature chart of case 3.

picture of a severe systemic disturbance culminating in severe rigor. A blood-culture taken at that time remained sterile, but the condition was that of a septicæmia and gave rise to considerable anxiety. On the afternoon of April 25, the patient was put on sodium salicylate, gr 30 six hourly. April 26 another severe rigor occurred, but next morning temperature was normal and it remained so. On April 28 myelism developed, and the administration of salicylate was abandoned. The local condition improved thereafter, rigors, and convalescence remained uninterrupted. The pus contained scanty gram positive cocci. A culture showed a growth of coagulase positive *Staph aureus* which had a penicillin sensitivity of 10. Radiography on April 28, showed a slight periosteal reaction in the lower quarter of the humerus, and rarefaction in the base of the ulnar styloid process, the condition being consistent with osteomyelitis under treatment."

DISCUSSION

The possibility of a synergistic action of penicillin and salicylate was considered, and in an in vitro experiment showing dilutions of penicillin were put up in parallel with similar dilutions of penicillin in a solution of sodium salicylate containing 40 mg per 100 ml. as the diluent. Oxford staphylococcus was used as the test organism. No significant difference was found. The possibility that large doses of salicylate might act directly on the kidneys and prevent the excretion of

Although the result in case A seemed to point to a delayed urinary excretion of penicillin, the results in cases B and C did not. It will be seen that the dilutions required were much the same whether salicylates had been given or not.

SUMMARY

In four cases of acute osteomyelitis striking clinical improvement followed the administration of large doses of salicylate. No explanation is at present offered for this effect.

DIMERCAPROL IN ACUTE LEAD POISONING

POUL BASTRUP-MADSEN

M.D. Copenhagen

ASSISTANT PHYSICIAN, ÅRHUS MUNICIPAL HOSPITAL, DENMARK

British anti-lewisite, BAL, or dimercaprol (2,3-dimercaptopropanol) has become of great clinical importance in the treatment of intoxications produced by arsenic, gold, and mercury, but it has not yet been thoroughly tested in lead poisoning.

Experiments made by Braun et al (1946) to ascertain the efficacy of dimercaprol in the therapy of intoxications by various metallic compounds in rabbits showed that it was an ineffective antidote in lead poisoning. On the other hand Chiodi and Sammartini (1947) found in white rats that dimercaprol prevented damage to the kidneys caused by lead compounds, but did not prevent anemia. Ryder et al (1947) found that two hours after a single injection of dimercaprol an increased amount of lead was present in the urine of people who had been exposed to lead during their work. Cases of lead poisoning treated with dimercaprol have been reported by Telfer (1947) and Sundlin (1948). In both cases the excretion of lead in the urine was increased without recurrence of the symptoms of intoxication.

I report here two cases of acute lead poisoning treated with dimercaprol. The lead analyses were done by Prof. Hakon Lund, Ph.D., of the chemical institute of the University of Århus.

Method of Treatment.—Dimercaprol was given in the dosage recommended by Carleton et al (1948): four doses of 0.1 mg in the first day, two doses of 0.1 mg from the second to the fourth day, and 0.1 mg on the fifth and sixth days. The preparation used was a 5% solution of dimercaprol in arachis oil containing 10% benzyl benzoate.

CASE RECORDS

Case 1.—A girl, aged 15, had taken a teaspoonful of litharge (lead monoxide) to induce abortion, and nine days later a second teaspoonful. In the next few days she complained of

Fig. 4—Temperature chart of case 4

penicillin was also investigated. Three patients, to whom purpose of the experiment had been explained, were given penicillin 50,000 units intramuscularly, and specimens of venous blood were collected at half-hour intervals for four hours. Next day sodium salicylate gr 30 was given four hourly and continued for forty-eight hours, after which an intramuscular injection of penicillin 500,000 units was given. The results were as follows:

CASE A		CASE B		CASE C

Fig. 1—Excretion of lead in case 1

increasing nausea and headache. Four days after the last dose of litharge she developed intermittent diffuse abdominal pain and was admitted to this hospital.

On admission the hemoglobin was 68% (Sicca), 0.2% of stippled cells were found. The urine contained porphyrin. The amount of lead excreted in the urine was 0.11–0.14 mg in twenty four hours.

Progress—During the first few days in hospital mild abdominal pain persisted, but it was so slight that it did not require treatment. The patient felt a little nauseated. On the third and fourth days in hospital the patient was given ammonium chloride 8 g daily, but did not respond with a definite increase in the excretion of lead. From the fifth day she was given a six day course of injections of dimercaprol, which led at once to a considerable increase in the excretion of lead in the urine (fig 1). The patient suffered no discomfort from the treatment, and the increased excretion of lead was not accompanied by any rise in the number of stippled cells.

Fig 2—Excretion of lead in case 2 (measured only in the first three days of treatment with dimercaprol)

was pale, with cyanotic lips. Her abdomen was tender but soft, palpation showed contracted intestines. Her blood pressure was 140/160, pulse rate 60, and hemoglobin 78% (Sicca). Her urine contained porphyrin. There was slight hematuria but no albuminuria. An eight-hour specimen of urine contained less than 0.05 mg of lead, the amount excreted in twenty four hours was therefore reckoned to be less than 0.15 mg.

Treatment and Progress—Dimercaprol therapy as previously described was then instituted. The excretion of lead in the following three twenty four hour periods was examined, and a definite increase was found (fig 2). At the start of the dimercaprol therapy the patient was lucid and oriented but complained of severe abdominal pain, which persisted for the next four days. It seemed as if the injections of dimercaprol neither aggravated nor mitigated the pain. Nor did calcium injections, nitroglycerin, or atropine affect the pain. Injections of morphine gave some relief. By the fifth day the pain had disappeared, and the patient felt quite well. At the end of the course of dimercaprol there was no hematuria, no albuminuria, and no porphyrinuria, but the hemoglobin was still reduced (67%).

DISCUSSION

The diagnosis of acute lead poisoning was established in these two cases. Both patients had taken litharge by mouth and showed typical symptoms of plumbism. In case 1 a two day treatment with ammonium chloride did not affect the elimination of lead. In both cases a considerable increase in the excretion of lead was seen immediately after the administration of dimercaprol, hence it can scarcely be doubted that the dimercaprol had promoted the excretion. The symptoms of intoxication were not aggravated by the treatment, as was the case in the treatment formerly used in mobilising the lead from the body. There is scarcely any reason to fear that in mobilising lead from the depots (in the bones or elsewhere) dimercaprol might exacerbate the toxic symptoms, for dimercaprol forms with the heavy metals

and arsenic non toxic and very stable compounds, which are quickly excreted (Peters et al 1945).

Therefore it seems reasonable to prefer dimercaprol to lead mobilising therapy with acidosis or parathyroid hormone, since the latter methods of treatment involve a risk of exacerbating the intoxication and are the contra indicated in the early stages of lead poisoning. Further, in mobilisation of lead by means of acidosis or parathyroid hormone the patient is exposed to the risk of protracted hypercalcaemia, which may very well have unfortunate consequences. Dimercaprol must be regarded as a rational and effective means of increasing the excretion of lead in acute lead poisoning.

Case 2 had very severe abdominal colic on admission. The attacks did not seem to be affected by the injection of dimercaprol. Thus, in severe lead intoxication, the individual intramuscular injections of dimercaprol will not detoxicate such large amounts of lead that the abdominal pain is relieved by each single injection.

It is necessary to investigate a large series of patients to determine whether dimercaprol therapy in promoting the excretion of lead can also shorten the duration of symptoms of plumbism.

SUMMARY

Two patients with acute lead poisoning following ingestion of litharge were treated with dimercaprol. In both cases the amount of lead excreted in the urine was considerably increased immediately after the institution of dimercaprol therapy. The mobilisation of lead did not seem to aggravate the symptoms of intoxication.

FATAL SALMONELLA INFECTION SIMULATING ENTERIC FEVER

SARAH CHARD

M.B. Wales

HOUSE SURGEON

ST WOOLOS HOSPITAL, NEWPORT, MON

DAVID STERN

M.R.C.S.

PATHOLOGIST

Salmonella tennessee was first isolated in the laboratories of the Tennessee Department of Health from the faeces of a normal carrier employed as a food handler, several people were affected with food poisoning, but no deaths were reported (Bruner and Edwards 1942). *S. tennessee* was also responsible for an outbreak of food poisoning in a military hospital in this country in 1947, about 20 people were affected, the disease was mild, giving rise to abdominal pain, cramps, and nausea, with vomiting in a

Small intestine showing transverse ulcers with perforations (indicated by white lines)

of the more severe cases, headache, and diarrhoea, no deaths were reported (Taylor 1947)

CASE RECORD

woman, aged 25, was admitted to this hospital on Oct 16, 1947 with a history of abdominal pain and constipation for twenty-four hours and vaginal bleeding for five days. The normal period had been in August. There had been massive bleeding in September, and vaginal bleeding had continued two weeks before admission and had continued intermittently since.

On examination the patient was very pale and lay on her left side. Temperature 98°F, pulse rate 120, blood pressure 110/72. The abdomen was rigid and tender, especially on the left side. There was much tenderness in the left fornix on vaginal examination. The size of the uterus could not be assessed, owing to the abdominal rigidity. The haemoglobin was 54%. A ruptured ectopic pregnancy was diagnosed. Operation—On laparotomy a left-sided ruptured tubal pregnancy was found. The left fallopian tube and ovary were removed, together with numerous intraperitoneal blood clots. The abdomen was closed without drainage. One pint of blood was given, and a course of systemic penicillin started.

Progress—For the first three days there was practically no change. The general picture was that of an anæmic woman, poor general health, progressing slowly after a severe intra-abdominal catastrophe. On the fourth day she complained of vomiting, diarrhoea, and upper abdominal pain. She was lethargic and had much abdominal tenderness and distension. Constipation was heard. Acute enteritis was diagnosed. The condition deteriorated steadily from this time, and the patient died on the tenth day. From the day of the operation till she died there was persistent pyrexia; the temperature fluctuating between 101° and 103°F. At no time did the patient develop a rash and no enlarged spleen could be felt, but otherwise the clinical picture resembled that of enteric fever. Faeces examined at the start of the diarrhoea yielded a salmonella on culture. This organism was referred to Dr Joan Taylor, of the Salmonella Reference Laboratory, and was subsequently identified as *S. tennessee*. Blood cultures were sterile.

Necropsy—Numerous transverse ulcers associated with perforations of the small intestine were found (see figure). There was a massive faecal peritoneal effusion. Cultures taken from the ulcers and mesenteric glands yielded *S. tennessee*.

No other case developed in the ward, and no attacks of mild diarrhoea were noted. Thorough investigation of the patient's home contacts did not reveal a carrier. So far as could be ascertained, the patient had not eaten any dried eggs.

DISCUSSION

In this first recorded death due to *S. tennessee* the morbid anatomical appearances were those of true enteric fever. It is presumed that a normally mild disease was fatal owing to the lowered resistance of a patient seriously ill from a ruptured ectopic gestation. Possibly, however, increased virulence of the organism played a part.

"What remedy, then, can be found for the physical and psychological debacle of the twentieth century? The answer is provided by the word leisure, yet extremes are difficult to avoid and dangerous when they develop. Today the brain worker is starved of leisure; that time for unburied thought, which is his life blood, while the manual operative is surfeited with time which he has not learned to employ to his own best advantage or to that of the society of which he is a unit. The former cannot produce what he would wish while the latter, like the Romans of old, is forced to demand more and more spectacles or distractions. Both mental and manual worker, the one through denial of opportunity, the other through lack of education, may with justice echo the lament of the dying Cecil Rhodes: 'So much to do and so little done.'—Dr A. P. MURPHY in presidential address to Australian Medical Congress *Med J Aust* July 15, 1950, p 69

New Inventions

A MODIFIED MAYO VEIN STRIPPER

MODERN opinion is not in favour of injections for idiopathic varices affecting the long saphenous system in the thigh. As scarification of the intima of the long saphenous vein has led in my practice to embolic phenomena, Mayo's vein stripper has been modified, a circular blade being substituted for the ring to obtain a clean division of the communicating veins (Fig 1).

Fig 1—Modified Mayo's vein stripper

shows the modified instrument. The shaft has been lengthened and the place of the smooth terminal ring taken by a circular blade 1 cm in diameter.

The operation begins with the modern Trendelenburg procedure. A no. 4 or no. 6 oesophageal gum-elastic bougie is next passed down the lumen of the long saphenous vein as far as the knee, a small transverse incision is made at this level, and the long saphenous vein is brought to the surface and divided, the lower end being tied. The upper end is brought out of the wound, and the bougie is pulled through the vein to the surface, the modified vein stripper is next passed over the bougie and vein, and the vein is fixed to the bougie with style forceps. The vein stripper, guided by the

Fig 2—Bougie in position for stripping

Fig 3—Vein stripper in position after stripping. Above bougie removed with stripped vein

bougie, is next pushed up the thigh, and the long saphenous vein is completely removed from knee to groin. Figs 2 and 3 show this manoeuvre, and fig 3 the excised varicose vein with clean division of the tributaries and deep communications.

It is important to operate with the patient in a 20° Trendelenburg position and to maintain the tilt of the table for half an hour after operation to minimise subcutaneous oozing.

The instrument has been made for me by Down Bros and Mayer & Phelps Ltd, and I wish to thank Dr K. B. Pinson, of the Manchester Royal Infirmary, who kindly made the original model for me.

Reviews of Books

Malignant Disease and Its Treatment by Radium

Vol. III (2nd ed.) Sir STANFORD CADE, K.B.E., O.B., F.R.C.S., surgeon, Westminster Hospital, consulting surgeon Mount Vernon Hospital and Radium Institute Bristol John Wright & Sons 1950 Pp 446 52s 6d

IN its new edition the third volume of this great work is again welcome for the wealth of clinical experience which the author has at his disposal. The chapter on cancer of the breast maintains the high level of the first edition but adds new material on methods of irradiation. Thoracic tumours are again dealt with by O. Price Thomas; he includes new chapters on X-ray therapy, but little description of the methods of irradiation nowadays used for cancer of the lung. There is a good clinical section on cancer of the stomach and oesophagus, but these are conditions in which radiotherapy plays little part in treatment. The chapter on cancer of the uterus has been extensively revised with the help of M. Lederman and now gives important facts about the doses received from different intracavitary arrangements of radium, the combination of X rays with radium, and the methods used for measuring dosage-rate when working with small ionisation chambers loaded in a special probe. The other gynaecological cancers are adequately covered, but the chapter on tumours of the ovary might well be extended to describe some of the more recent methods of treatment and their results. Improvement in methods of treatment of cancer of the bladder are discussed, but the figures given are out of date, and do not reflect the advances achieved by the use of radium in suitable cases. On the other hand, in the section on treatment of cancer of the rectum, a good deal of space is allowed to some radiotherapeutic measures which have been completely discarded.

The volume as a whole takes a worthy place with the rest of this standard textbook.

Stomach Disease as Diagnosed by Gastroscopy

EDDI D. PALMER, M.S., M.D., major, Medical Corps, United States Army London Henry Kimpton 1949 Pp 200 42s

Major Palmer has endeavoured to supply a need in bringing together in one volume the gastrosopic descriptions of various diseases. His enthusiasm has led him into a discussion of every known gastric condition, with extensive quotation from other authors. The subject of gastritis is made no simpler, though there is an unusual section on post-irradiation and post-vagotomy appearances in the stomach. Not every gastrosocist would agree that the postoperative stomach shows a diffuse purulent gastritis or that atrophic gastritis may coexist with rugae of normal size. The practice of gastrosocopy, however, being in its early years, is beset with differences of opinion. Dr Palmer has published his own experiences in this book.

Water and Salt Depletion

H. L. MARRIOTT, O.B.E., M.D., F.R.C.P., physician to Middlesex Hospital, London Oxford Blackwell Scientific Publications 1950 Pp 80 15s

THIS reprint of Dr Marriott's 1946 Croonian lectures is most welcome. It forms an excellent introduction to the subject of water and salt depletion and gives a fair survey of the literature up to (though unfortunately not later than) 1946. In the author's words, "water and salt are perhaps practically the most important substances it is in our power to administer", and his book tells, in simple language, why and when they should be administered.

The signs and symptoms of water deficiency are well known and nearly always recognised, but the type of dehydration due to salt deficiency can develop just as easily, even in a non-tropical country. Dr Marriott shows how injudicious treatment may first give rise to and then aggravate salt deficiency dehydration. Impending salt deficiency is reflected first by a fall in the urinary chloride excretion: a patient suffering from salt-deficiency dehydration may have a normal or near-normal concentration of chloride in his plasma, but his urine may be chloride free. Hence the importance of

the routine performance of simple approximately quantitative tests for urinary chloride, such as the Fil-test. Most doctors with tropical experience have patients suffering from a combined salt and deficiency, unable to retain fluids by mouth, or, when failing to get relief from oral administration of salt. Dr Marriott suggests that in salt depletion there is pylorospasm, gastric retention, and subsequent vomiting, thus a vicious circle is set up which accentuates the deficiency—a suggestion which merits careful and serious consideration.

Turning to details, it is somewhat surprising to find mention of the work of Elkinton and Winkler, and the use of the adrenal cortex is referred to only very briefly. The copper sulphate method of determining blood and plasma specific gravities is described a little misleadingly as a "drip drop" method, while the Lindstrom-Lang gradient for the same determination is not mentioned.

Human Ability

By C. SPEARMAN, PH.D., LL.D., F.R.S., and L. WYLLIES JONES, M.A., PH.D., D.Sc. London Macmillan 1949 Pp 198 16s

Professor Spearman had intended this to be a continuation of his *Abilities of Man*, which appeared in 1927, a great part of the work had been written by him before his death. It is in large measure an expansion and corroboration of what he has written in the earlier book. The discussion is technical, direct, and vigorous; it is not likely to be of interest to those who have not a professional concern with the statistical approach to psychological problems. It is noteworthy that after marshalling the evidence, Professor Spearman concludes that the general factor G, which has been so closely associated with his name, presents at least the cardinal statistical characters—definiteness, comprehensiveness, and stability—which are indispensable for the purposes of science, and that it is "essentially characterised by the combination of noogenesis with abstractness", in their concluding remarks the authors put forward the hypothesis that G represents the amount of mental energy. The book as a whole is an impressive testimony to the volume of work that has developed out of Spearman's pioneer researches.

Electrotherapy and Light Therapy (6th ed. London Henry Kimpton 1949 Pp 739 70s).—Prof. Richard Kovacs's useful textbook contains chapters on massage, exercise, hydrotherapy, and treatment by cold. It is up to date, and even has a brief but useful section on the possible therapeutic uses of ultrasonic waves. An extensive section on the application of physical methods of treatment carries articles by authorities on special subjects. Though Professor Kovacs's support of the methods of physiotherapy is wholehearted, his book is laudably free from exaggeration. Some divergences between English and American practice may be noticed: thus micro-wave diathermy, which has not yet received much support here, is fully described, and the accuracy of passive exercise and manipulation will seem unorthodox to British readers. The chapters on electrophysiology and electrodiagnosis (with a useful description of electrocardiography) may be specially recommended.

Lehrbuch der inneren Medizin (Stuttgart Thienemann 1950 Vol. I Pp 999 D.M. 29.70).—This volume of just under 1000 pages covers mainly diseases of the blood, diseases of metabolism and respiration, infectious diseases, and diseases of bones and joints. Edited by Dr. Helmut Dennig, of Stuttgart, and written by ten authors, some of whom are well known to English readers, it is well up to pre-war standards, showing all the thoroughness and detail expected of a German textbook. The subject matter is presented fully and explicitly, and rare diseases are included with no notable omissions. It is very pleasantly up to date and includes quite lengthy accounts of many recent advances, such as the use of streptomycin and p-aminosalicylic acid together in pulmonary tuberculosis, though it does not quite reach to the use of B₁₂ in pernicious anaemia. The illustrations are good, and the book may be regarded as an authoritative and comprehensive major German textbook of medicine. There is an introduction, so it is not clear how many more volumes are to be expected to complete the work.

THE LANCET

LONDON SATURDAY, JULY 29, 1950

The Aseptic Management of Burns

To LISTER's opponents antiseptics, and later asepsis, are anathema not because they were nonsense (though that was the war cry) but most probably because they looked like being an intolerable nuisance. Asepsis in the operating-theatre is still a nuisance; still means endless preparation, constant vigilance, still unserving attention to detail on the part of doctors, nurses, surgeons, assistants, anaesthetists, students—everyone in fact who comes near the patient. Experience has shown the nuisance to be not only tolerable but essential, and nowadays anyone who flouted the rules would be roundly and rightly condemned by his fellow professionals. Here, then, is an example of the good habit triumphant over a troublesome purposeful ritual endured for, and wholly justified by, its results.

This lesson took time to learn, but once learnt it was universally applied, and now Dr LEONARD COLEBROOK¹ tells us it is time—and high time too—that we learned it afresh, and applied it to the treatment of burns. His argument is extremely cogent. To present the almost universal plan is to admit burned patients to a general hospital. The surgeons do not want them in the ordinary surgical wards because more often than not they become infected and are a danger to clean cases. To admit them to the aseptic wards is to invite infection of the burns and embrace defeat at the outset. Some hospitals admit them to a separate ward of their own, but without elaborate precautions against cross infection from case to case, and without specially experienced staff able to give much time to them, this too is unsatisfactory. Streptococcal infection is apt to become the rule in such wards, and the surgeon is then greatly handicapped in his treatment. The badly burned or scalded patient is a serious emergency, in as much danger of death from mismanagement as a patient with acute appendicitis. Such a case, Dr COLEBROOK says, should be the direct responsibility of a trained surgical team alive to both the difficulty and the necessity of preventing infection. He holds, and we agree with him, that if burned people are to get the treatment which gives them the best hope, first of life and then of functional recovery, we must set up one or more burns centres, preferably attached to hospitals, in every large city. He bases his confidence in this plan on his experience as director of the Medical Research Council burns unit of the Birmingham Accident Hospital, from which he retired in 1948. And he compares the lot of a burned patient sent to such a

centre with that of one sent to a general hospital. The two pictures, drawn sparingly and with detachment, are worth considering carefully.

The staff at the burns unit start with the knowledge that, despite the difficulties, infection can be prevented in the great majority of burns and scalds. The patient—usually a child, and usually a girl—is seen in the casualty department within 10 minutes of her arrival, either by the senior surgeon of the burns centre or his deputy, who notes in a quick glance the extent of the injury. The burned areas are then covered with a large sterile towel and lightly bandaged, and the child is sent immediately to the "shock room," the air of which has been filtered and warmed, and brought in under slight pressure from the roof, so as to limit the chances of airborne infection. Since shock develops quickly with any extensive burn, she is at once given a plasma drip through a cannula, so within half an hour of admission she has already had several ounces of plasma into a vein and is getting sips of fluid by mouth. A sample of blood, taken before the drip started, yields a haemocrit estimation within half an hour, and further estimations are made every 2 or 3 hours to guide the surgeon in deciding how fast to give the plasma and when to stop it. He visits her at short intervals during those hours, and a special nurse remains with her to comfort her and give her frequent sips of fluid, as well as to look after the drip and watch her condition.

When she is fit—usually after 4-6 hours—her burns are dressed quickly in the shock room by a trained team, all completely covered by sterile clothing and using a strict no touch technique. If the burn is likely to weep a sheet of 'Cellophane' or special 'Nylon' is included in the dressing to prevent organisms growing through from the outside, and if the dressing might slide, or be moved by the child, a plaster-of-paris shell is put round the outside. The treatment which Dr COLEBROOK regards as most successful in keeping a burn free from infection is gentle cleansing with a detergent solution, and a bland non-toxic application incorporating penicillin.

At the end of 24-36 hours, if the child continues to improve she is moved into a single-bed cubicle, with cross ventilation, opening on a balcony. She now has a good chance of avoiding cross infection, and unless the dressings become fouled with excreta they are not changed for a week or more, during which time the child should be nearly, or quite, afebrile and fairly comfortable. The next dressing is done by the surgeon, in whom she now has confidence, and it causes little pain because the tissues are not inflamed. If bacteriological examination at the second and third dressings shows the wounds to be free from streptococci, skin grafting is done 15-20 days after the accident, and with an experienced surgeon 90% of the grafts take. Dressings then become almost painless and healing is complete within 6-8 weeks of the accident. Any slight contractures which may develop can be dealt with early.

So much for the routine at a good burns unit. What usually happens, however, is that the child is admitted to a general hospital which gets only a few bad burns in the year, and makes no special provision for them.

She is seen in the casualty department, commonly by a junior surgical officer who telephones the house-surgeon and sends her into a ward. This may take 15 minutes. The surgeon under whose care she is admitted may not be in the hospital or may be operating, and the house surgeon may be detained by other work—which he may wrongly believe to be more urgent—and may not see her for an hour. He often has had no experience of a severe burn, and does not realise that the child's life depends on the immediate treatment of shock by fluid replacement. He dresses her burns in the open ward, often without using a strict no touch technique. He rarely has enough crepe bandages for his needs, and so uses cotton ones which will work loose. Her condition now being poor, he decides to set up a plasma transfusion, but has difficulty because all the veins are collapsed. An hour or two may be wasted in getting the cannula into the vein and establishing a steady flow. Since it is now

Reviews of Books

Malignant Disease and its Treatment by Radium

VOL III (2nd ed) Sir STANFORD CADE, K.B.E., O.B., F.R.C.S., surgeon, Westminster Hospital, consulting surgeon Mount Vernon Hospital and Radium Institute Bristol John Wright & Sons 1950 Pp 446 52s 6d

IN its new edition the third volume of this great work is again welcome for the wealth of clinical experience which the author has at his disposal. The chapter on cancer of the breast maintains the high level of the first edition but adds new material on methods of irradiation. Thoracic tumours are again dealt with by O. Price Thomas, he includes new chapters on X-ray therapy, but little description of the methods of irradiation nowadays used for cancer of the lung. There is a good clinical section on cancer of the stomach and oesophagus, but these are conditions in which radiotherapy plays little part in treatment. The chapter on cancer of the uterus has been extensively revised with the help of M. Lederman and now gives important facts about the doses received from different intracavitary arrangements of radium, the combination of X rays with radium, and the methods used for measuring dosage rate when working with small ionisation chambers loaded in a special probe. The other gynaecological cancers are adequately covered, but the chapter on tumours of the ovary might well be extended to describe some of the more recent methods of treatment and their results. Improvement in methods of treatment of cancer of the bladder are discussed, but the figures given are out of date, and do not reflect the advances achieved by the use of radium in suitable cases. On the other hand, in the section on treatment of cancer of the rectum, a good deal of space is allowed to some radiotherapeutic measures which have been completely discarded.

The volume as a whole takes a worthy place with the rest of this standard textbook.

Stomach Disease as Diagnosed by Gastroscopy

EDDY D. PALMER, M.S., M.D., major, Medical Corps, United States Army London Henry Kimpton 1949 Pp 200 42s

Major Palmer has endeavoured to supply a need in bringing together in one volume the gastroscopic descriptions of various diseases. His enthusiasm has led him into a discussion of every known gastric condition, with extensive quotation from other authors. The subject of gastritis is made no simpler, though there is an unusual section on post-irradiation and post-vagotomy appearances in the stomach. Not every gastroscopist would agree that the postoperative stomach shows a diffuse purulent gastritis or that atrophic gastritis may coexist with rugae of normal size. The practice of gastroscopy, however, being in its early years, is beset with differences of opinion. Dr Palmer has published his own experiences in this book.

Water and Salt Depletion

H. L. MARRIOTT, O.B.E., M.D., F.R.C.P., physician to Middlesex Hospital, London Oxford Blackwell Scientific Publications 1950 Pp 80 15s

THIS reprint of Dr Marriott's 1946 Croonian lectures is most welcome. It forms an excellent introduction to the subject of water and salt depletion and gives a fair survey of the literature up to (though unfortunately not later than) 1946. In the author's words, "water and salt are perhaps practically the most important substances it is in our power to administer", and his book tells, in simple language, why and when they should be administered.

The signs and symptoms of water deficiency are well known and nearly always recognised, but the type of dehydration due to salt deficiency can develop just as easily, even in a non-tropical country. Dr Marriott shows how injudicious treatment may first give rise to and then aggravate salt-deficiency dehydration. Impending salt deficiency is reflected first by a fall in the urinary chloride excretion, a patient suffering from salt-deficiency dehydration may have a normal or near-normal concentration of chloride in his plasma, but his urine may be chloride-free. Hence the importance of

the routine performance of simple approximate quantitative tests for urinary chloride, such as the Fick test. Most doctors with tropical experience have patients suffering from a combined salt and water deficiency, unable to retain fluids by mouth, or, when failing to get relief from oral administration of salt. Dr Marriott suggests that in salt depletion there is pylorospasm, gastric retention, and subsequent vomiting, thus a vicious circle is set up which accentuates the salt deficiency—a suggestion which merits careful and serious consideration.

Turning to details, it is somewhat surprising to find mention of the work of Elkinton and Winkler, and that of the adrenal cortex is referred to only very briefly. The copper sulphate method of determining blood and plasma specific gravities is described a little misleadingly as a "fall drop" method, while the Lundstrom Lang gradient for the same determination is not mentioned.

Human Ability

By C. SPEARMAN, PH.D., LL.D., F.R.S., and L. W. JONES, M.A., PH.D., D.Sc. London Macmillan 1950 Pp 198 16s

Professor Spearman had intended this to be a continuation of his *Abilities of Man*, which appeared in 1927, a great part of the work had been written by him before his death. It is in large measure an expansion and corroboration of what he has written in the earlier book. The discussion is technical, direct, and vigorous, it is not likely to be of interest to those who have not a professional concern with the statistical approach to psychological problems. It is noteworthy that after marshalling the evidence, Professor Spearman concludes that the general factor G, which has been so closely associated with his name, presents at least the cardinal statistical characters—definiteness, comprehensiveness, and stability—which are indispensable for the purpose of science, and that it is "essentially characterised by the combination of noogenesis with abstractness" in their concluding remarks the authors put forward the hypothesis that G represents the amount of mental energy. The book as a whole is an impressive testimony to the volume of work that has developed out of Spearman's pioneer researches.

Electrotherapy and Light Therapy (6th ed. London Henry Kimpton 1949 Pp 739 70s) —Prof. Richard Kovacs's useful textbook contains chapters on massage to exercise, hydrotherapy, and treatment by cold. It is up to date, and even has a brief but useful section on the possible therapeutic uses of ultrasonic waves. An extensive section on the application of physical methods of treatment came from articles by authorities on special subjects. Though Professor Kovacs's support of the methods of physiotherapy is wholehearted, his book is laudably free from exaggeration. Some divergences between English and American practice may be noticed, thus micro wave diathermy, which has not received much support here, is fully described, and the account of passive exercise and manipulation will seem unattractive to British readers. The chapters on electrophysiology and electrodiagnosis (with a useful description of electromyography) may be specially recommended.

Lehrbuch der inneren Medizin (Stuttgart Thien 1950 Vol. I Pp 999 D.M. 29.70) —This volume of just under 1000 pages covers mainly diseases of the blood, diseases of metabolism and respiration, infectious diseases, and diseases of bones and joints. Edited by Dr. Helmut Dennig, of Stuttgart, and written by ten authors, some of whom are well known to English readers, it is well up to pre-war standards, showing all the thoroughness and detail expected of a German textbook. The subject matter is presented fully and explicitly, and rare diseases are included with no notable omissions. It is very pleasantly up to date and includes quite lengthy accounts of many recent advances, such as the use of streptomycin and p-aminosalicylic acid together in pulmonary tuberculosis, though it does not quite reach to the use of B₁₂ in pernicious anaemia. The illustrations are good, and the book may be regarded as an authoritative and comprehensive major German textbook of medicine. There is an introduction, so it is not clear how many more volumes are to be expected to complete the work.

the cause of the anæmia in these cases is bleeding from the herniated portion of the stomach. Occasion-ally there is a traumatic ulcer—2 of the 20 cases reported by SCHWARTZ and BLUMENTHAL⁵ had one—

BOCK and his colleagues⁶ showed that the finding is usually a sort of gastrostasis, arising from multiple congestion of the mucosa with enlarged veins in the underlying wall, and subsequent investigations have confirmed their opinion. A considerable proportion of the patients with diaphragmatic hernia in hospital have had a serious amount of bleeding as COWAN⁷ in New York reported 45 cases of diaphragmatic hernia of which 13 had a severe secondary anæmia. He remarked that in the anæmic patients "the presenting symptoms are those usually associated with severe anæmias, such as weakness, anorexia, dyspnoea, and pallor. Very few any gastric symptoms are associated with the anæmia. The case histories of all these patients show the presence of a long standing secondary anæmia without evidence of bleeding from the alimentary tract and due to ulcers, varices, or any other organic disease." His acute observation shows why the association of anæmia with hernia of the stomach is so often missed—until radiology provides the answer. This combination has been seen in children. Thus CHRISTIANSEN⁸ reported a case of hæmatemesis and hiatus hernia in a child of 1 year, and BERGENFELDT⁹ noted the same syndrome in a boy of 18 months who was successfully treated by repair of the hernia. But most of the patients are elderly and female; for example, BOUSSER¹⁰ in France reported 6 cases, all in females, aged 41–72 years, and of the 20 cases reported by SCHWARTZ and BLUMENTHAL¹² were in females and only 1 woman and 2 men were under 50. The hæmoglobin in these 20 American cases was very low, ranging from 2.2 to 7.3 g, and 11 cases had less than 5 g per 100 ml. The colour index was 0.70 or less in 16 patients, the other 4 had had recent acute hæmorrhages. Only 2 had had hæmatemesis, 2 had fresh blood in the stools, 2 had tarry stools, and only 4 others had a positive occult-blood test in the stools. Twelve of the patients had symptoms referred to the abdomen, but these were not severe, in fact, cardiovascular symptoms were much more prominent.

The treatment, ideally, would be surgical repair of the hernia and return of the herniated stomach to the abdominal side of the diaphragmatic division. This has been done successfully in the younger cases. But in the patients over 60 the advisability of operation is doubtful. Fortunately, as SCHWARTZ and BLUMENTHAL show, nearly all the patients respond well to iron, in only one of their patients, a woman of 77, was the improvement in the anæmia slow, and this was because of continued gastro-intestinal hæmorrhage, in the others the response was often dramatic. Evidently the drain on iron stores is slow and there is no absorption defect to interfere with treatment. Even those who do not respond well to iron by mouth are likely to improve with the new intravenous preparations.

Annotations

UNIFORM ACCOUNTS FOR HOSPITALS

THE Ministry of Health is now requiring all hospitals to adopt a uniform system of hospital accounting.¹ This is described as a "relatively simple subjective analysis of expenditure" and it is explained that a more advanced costing technique may need to be developed later to provide data required in respect of "the large multi-purpose general hospital, where the costs of the various departments are of major importance in effecting comparisons with other hospitals." In other words, the present proposals are a refinement of the traditional system, and departmental costing will have to await the pilot inquiry now being undertaken by King Edward's Hospital Fund for London and the Nuffield Provincial Hospitals Trust.

An attempt is, however, being made to improve the old system. The analysis under headings of the traditional type—dressings, drugs and provisions, salaries and wages (medical, nursing, &c.)—has been pressed further, and many categories hitherto grouped together have been separated out to facilitate comparison between different hospitals. Thus, for example, salaries and wages are now to be split into some ten separate headings so that such an item as catering staff is taken as a unit and includes catering officers, dietitians, chefs, cooks, and kitchen staffs. Two further steps are to be taken. First an attempt is made to arrive at an assessment of the expenditure on outpatients in order that this disturbing factor may be eliminated. "It is appreciated," it is said "that true outpatient costs can only be ascertained by detailed departmental cost accounting," but a notional elimination of these costs is to be sought by adopting the former E.M.S. basis of five outpatient attendances equalling one inpatient day. This is an old trouble. Fifty and more years ago Sir Henry Burdett used to try to persuade hospitals to keep accurate figures for outpatient expenditure, but had to fall back on a formula—"that the cost of treating 1000 outpatients is about equal to the expenditure on one occupied bed." By 1905 this was regarded as five times too many. The figure now adopted by the Minister is just about as arbitrary, and Burdett's lament is still applicable.

"The system is but a makeshift. It is humiliating to be obliged to make this confession, but until the managers of the various institutions keep separate accounts of the actual expenditure on inpatients and outpatients to enable them properly to enforce economy throughout each establishment.

It is unnecessary to complete his sentence. Secondly a new effort is being made to compute a vacant bed factor "which is assumed to be the difference between the cost per patient week and the cost per staffed bed week of standing charges, including extraordinary and Regional Hospital Board expenditure." It is a praiseworthy attempt to bring under control one of the factors which disturbs comparisons. Without sample figures it is difficult to see how it will work out in practice or exactly what use can be made of the figures.

The hospital accounts on this somewhat improved basis are to be forwarded to the regional hospital boards by Aug. 31 in each year, and regional hospital boards are asked to summarise the statements for submission to the Ministry of Health by Sept. 30. Boards of governors of teaching hospitals are also to send their completed statements to the Ministry of Health by Sept. 30. What is then going to happen to them? Apparently they are never to see the light of day. Free access to published comparative figures has been one of the greatest helps available to the hospital administrator of the past.

4 or 5 hours since the accident, the child's condition is grave, and in his anxiety he may run the plasma in too fast and risk giving her pulmonary cedema. In a busy ward no nurse can be spared to sit with her and give her sips of water or to chart her pulse, temperature, and respiration at half-hourly intervals. Probably no blood has been taken for a hæmatocrit estimation, if it has, the report will probably not come back till the next day, and the test is not repeated every 2 or 3 hours as it should be.

For the next 3 or 4 weeks the child, if she survives, will be very ill, her wound has become infected with streptococci from the air of the ward, and she has high fever. Dressings cause intense pain. After many weeks the burns may be fit for grafting, but she may have little sound skin left to make large grafts, and her surgeon may have had insufficient practice in grafting technique. If the first grafting fails others may fail also, for the granulations now have a tough and fibrous base. Healing over several months, she develops contractures which may leave her with crippling deformities for life. This story is not exaggerated, and it makes the case for the establishment of burns units something more than a nice idea for the future.

Dr COLEBROOK has given a great deal of thought to the way in which such units should be laid out, and his detailed scheme is illustrated by a tentative plan of a treatment block. The aims to be achieved are that all dressings should be done in "clean" air (that is, dust free air almost devoid of micro-organisms), that they should be done by a trained team using aseptic technique, that chemotherapy should be used and constantly checked by bacteriological findings, that patients should be nursed in properly designed cubicles, that the bacteriologist should act as "infection control officer" and should have a day-to-day liaison with the unit, and that an operating-theatre and anæsthetist should always be available, so that grafting can be done at the best moment. (In many cases this would be on the day of the accident.) The centre, he believes, should be part of a general hospital, depending on it for such things as anæsthetics, radiology, and laboratory investigations. The building would hold three sectors: sector A, for the treatment of outpatients, and the aftercare of inpatients; sector B, for the early non-operative treatment of fresh burns which are to be admitted to the wards; and sector C, for the later treatment of inpatients, and all those who need operative repair. Dressing and treatment rooms in all three sectors would be air-conditioned and reached by way of an air-lock.

On admission to the centre a case would be classified as slight, moderately severe fresh burn, moderately severe old burn (more than 12 hours old, and probably infected), or severe fresh burn. Slightly burned patients would go to sector A for dressing. Those with moderately severe burns would go to sector B, to the clean (air conditioned) admission room where their clothes would be removed and the burns covered by a sterile towel, and thence into the plenary treatment room, reserved for the first dressing of all fresh burns. After being dressed, patients would be taken to cubicles in the wards, or—if suitable for immediate grafting—back to the clean admission room, and thence to the theatre in sector C. After grafting they would, of course, go into cubicles. Those with moderately severe old burns would go to the "dirty" (but air conditioned) admission room in sector C, and thence to the main dressing station, and so to a cubicle. Thus early uninfected cases would

never enter a room that had been used for the treatment of an old case. Air conditioning in dressing rooms can be so arranged that 15 minutes after a patient has left the room there are no more organisms in the air than there were before the dressing started. The minutiae for avoiding any contamination of the burned area are set out by Dr COLEBROOK with the thoroughness which comes only of long experience of the dangers, and an imagination trained to outflank the unexpected.

The treatment of a burn is always in some sense an occasion of defeat, for nearly all burns, and particularly the burns of children, could have been prevented. Dr COLEBROOK has long been fighting for the fireproofing of materials, for the guarding of open electric fires, and for more general awareness of the danger, which would cut down our 2000 deaths a year and prevent much severe pain. But some lives and much pain could be saved, and many crippling deformities avoided, if every burned person could have the care of a well-trained team in a well-equipped unit. The case mortality at the Birmingham Accident Hospital for 241 burned children, in 1946-47, was 1.7%. This may be compared with the mortality for 366 hospital cases in Edinburgh during 1938-42, of 4.9% (10.3% for children with burns and 3.7% for scalded children).² The proper care of these patients means extra trouble, just as aseptic surgery meant extra trouble, but it is trouble which we cannot justifiably avoid.

Diaphragmatic Hernia as a Cause of Anæmia

ANÆMIA of the iron deficiency type is very common in women over 40. Most of these cases are primary anæmias, but some are the result of chronic loss of blood, either uterine, from a local lesion or menopausal "flooding," or gastro-intestinal. Among the unusual causes of bleeding from the alimentary tract is diaphragmatic hernia, and this is not likely to be suspected unless the doctor knows of its association with anæmia, since the symptoms are seldom helpful. However, it deserves to be included among the conditions to be looked for, because diaphragmatic hernias are not really very rare. As long ago as 1912, GIFFIN³ collected 650 published cases, though only 15 of them had been diagnosed during life. Since radiography of the alimentary tract has become commonplace, some 1-3% of these examinations have revealed a diaphragmatic hernia, and at the Mayo Clinic alone 600 cases were diagnosed⁴ between 1926 and 1941. Much the commonest form is herniation of the stomach through the oesophageal hiatus; other types result from congenital abnormalities such as short oesophagus or absence of the posterior part of the left diaphragm, and various abdominal organs have been known to get through into the chest. The typical patient with a diaphragmatic hernia is a short stocky elderly woman with symptoms suggesting cholecystitis or peptic ulceration—epigastric pain, flatulence, fullness after meals, or heartburn. The condition has been confused with coronary disease because it may cause substernal pain radiating to the left arm. True regurgitation of food, or epigastric pain brought on by lying down, should always suggest hiatus hernia.

er investigated the relation between water and salt sorption. Urea and mannitol were used as osmotic

tics so that the urinary volume was increased some but there was only a trivial increase in NaCl and CO_2 excretion. Thus in the rat sodium and water sorption are largely independent. The contents of proximal tubules and loops of Henle are isosmotic, water is presumably passively reabsorbed preserving osmoticity as the solids of the glomerular filtrate pass through the tubular cells. This finding outmoded Marshall's theory that the loops of Henle were the main site of osmotic work for water reabsorption. In fact it seems to play the part more of osmotic diluters, so their contents reach the distal tubules isotonic with plasma.

The maximum reabsorptive capacity of the distal tubules for both water and salt may be limited by critical constants. If this is true and the reabsorption of sodium in the proximal tubules is constant, sodium loss in the urine will depend on glomerular filtration rate. Such an assumption is supported by Marshall's theory, which is now fairly generally accepted, that the sodium retention of chronic congestive heart failure is due to reduced glomerular filtration rate but research techniques are needed to study this before a point can be settled.

Dr Homer Smith ended his narrative on a more homely and reassuring note by stating his belief that urea and creatinine clearances are still very useful clinically, even though they lack the refinements of research methods, and though the creatinine clearance in particular is hard to interpret in the presence of heart failure.

HOPEFUL SIGNS IN MENTAL NURSING

PSYCHIATRY is pre-eminently a field in which the best medical attention and treatment can be nullified by poor nursing, but the most conscientious nurses cannot fail to give poor service if they are pushed beyond reasonable limits. The reports of the Board of Control and more recently of the Minister of Health, have been depressing in their repetition of complaints that treatment of mental illness is being held up by a desperate shortage of nurses. There is now some evidence that the vicious circle of wastage—longer hours—increased wastage is being broken. In the years 1937–43 the average wastage of student nurses from mental hospitals was higher than in any other type of hospital.¹ It stood at the distressing figure of 82%, while the tuberculosis sanatoria lost 5% and the general hospitals lost 37%. Over the past twelve years there has been a dramatic fall in the intake of female mental nurses. In 1938 it was 9600 but in 1945 had fallen to 2400. Since the inception of the National Health Service this trend seems to have been reversed. It is difficult to compare figures, because they are now collected and arranged differently, but some conclusions can be drawn from the fact that there was an increase of 600 nurses in training (all types of hospitals) between July, 1948, and December, 1949 and an increase of nearly 1000 in the total nursing staff in mental hospitals. In mental-deficiency institutions, on the other hand, only 63 nurses in the same period.

It is difficult to assess requirements, because not only are most mental hospitals understaffed for their present commitments, but most of them ought to increase their beds. Even if nurses were available to staff these beds it is by no means certain that the money to maintain them would also be forthcoming. The recent cuts in estimates may force mental hospitals to close some of the beds they already offer. The present shortage of nurses might then even be eased for a time. Bearing all these variables in mind it is possible to estimate the present need at roughly 8000 (2000 of them males).

In recruitment the mental hospitals have to fight a public opinion which still thinks in terms of asylums where all hope is lost. At the Schoolgirls' Exhibition, held in London last month, a mental hospital was for the first time represented in the nursing section. The Claybury Hospital stand attempted "to enlighten the public as to conditions in mental hospitals and to recruit girls into the profession of mental nursing." In accordance with this double purpose, the stand showed modern instruments of treatment—such as apparatus for electric-convulsive therapy, and leucotomies—besides instruments used at Hanwell in the last century for mechanical restraint. Occupational therapy work, and photographs of the hospital departments and wards gave an impression of cheerfulness and hope. The exhibit which attracted most attention was one of intensely dramatic free-expression painting by a schizophrenic girl, the series showing unmistakable improvement to the most unpractised eye.

Opinions vary on the exact value of this type of exhibition. It seems probable that as far as immediate recruitment is concerned, it preaches only to the converted. But better understanding of the increasing hope in psychiatric treatment must surely bring a response in the future. The medical and nursing professions are largely to blame for public ignorance, and there is a good deal of ignorance among doctors and nurses themselves. The Ministry of Health is hoping to produce a short documentary film which will emphasise that insanity is merely a form of illness, and that much can be done for it. It will be some time before this can be made, but in the meantime there is plenty of room for other types of educational propaganda such as that offered by the National Association for Mental Health.

RADIOTHERAPY OF CANCER IN THE MOUTH

A Medical Research Council team, headed by Dr Constance Wood and Mr J W Boag, B.Sc., and drawn from the council's Radiotherapeutic Research Unit, has been comparing the efficacy of gamma rays and X rays in the treatment of cancer in the mouth. Their report,¹ now published, was eagerly awaited because of the urgent need to decide whether money would be better spent on the development of radium beam units in all major centres or on other forms of apparatus. Human therapeutic experiments that will satisfy the statisticians are always difficult to devise and to carry out, but in these trials careful planning, with strict standards of comparison and physical control, ensured complete accuracy within the limits set. The comparison made was between the gamma beam from 10 grammes of radium and an X-ray beam at 180 kV, so arranged that the isodose curves of the two types of radiation were almost perfectly matched. Beam direction was obtained by using treatment callipers, and tumour dose was calculated with measuring callipers or with the contour finder devised for the purpose and described in the report.

Statistical analysis, with special methods of estimating survival rates, has given the following results. The estimated cure rate at 5 years for patients treated with the radium beam is 31% (the actual survival rate at 4½ years which was not known until after the report was written, is 28%), and with the X-ray beam 19.2% (actual survival rate at 4½ years, 20%). The difference between the 5 year rates is 11.8%, which is less than 1.62 times its standard error and therefore not significant. The final conclusion reached in the report—"This investigation does not show that the wavelength of the radiation per se, within the limits of the experiment, has any significant effects on the clinical results."

¹ Report of the Working Party on the Training and Recruitment of Nurses, 1947.

¹ Researches on the Radiotherapy of Oral Cancer. *Spec. Rep. Ser. med. Res. Coun. Lond.* no 267. 1950. H. M. Stationery Office. Pp 148. 12s. 6d.

So and so shows a low figure for such and such a heading—how does he manage it? This kind of thing can exert a great influence in the right direction. One is bound to suspect that if the figures are never published much of this keenness to excel will be exchanged for a scrutiny by officials not themselves engaged in the actual administration of hospitals. This is a move backwards rather than forwards, but it is one that could easily be set right by a decision to make an exception to governmental practice in the case of hospital accounts and publish the figures.

DEVELOPMENT OF MODERN RENAL PHYSIOLOGY

ADDRESSING the lately formed Renal Association on July 15, Dr Homer Smith, of New York, gave a lively account of the development of our knowledge of renal physiology, beginning with the European work of Heidenham, Ludwig, Starling, and Cushny, and concluding with the more recent American advances of such men as Richards, Marshall, Walker, and (though he did not mention it) the speaker himself.

Modern theories of urine formation, he said, owe their first scientific support to Cushny, who separated the wheat from the chaff of much of the older work. He brought to light the controversy between the supporters of the secretion and the filtration with reabsorption theories, casting his own lot with the latter. Instead of crediting the renal tubules with powers of apparently purposeful selection which amounted almost to vitalism, he assumed that they reabsorbed a fluid of constant composition. In 1917 Richards, on a war time mission to England, met Cushny, and his work with Cecil Drinker gave him the experience of perfusion experiments which he was then able to apply to the kidney. Thus began the work of Richards and Plants on the "adrenaline paradox." They found that adrenaline increased the resistance to perfusion of an isolated kidney, but that at the same time the kidney volume increased. This they explained by assuming that adrenaline constricted the efferent glomerular arterioles more than the afferent ones, but we now know that adrenaline constricts not only these two types of vessel but also (most powerfully of all), the venules, thus damming back the blood in the organ. Inspired by Krogh's studies of frog capillaries Richards and Schmidt sought to test this hypothesis by direct microscopical observation. Though this work did not achieve the result they hoped for, it did lead to the observation of the intermittent activity of the frog kidney glomeruli. This concept tended to be transferred to the mammalian kidney, but, as was shown later, without justification. In amphibia the control of diuresis is probably exercised by changing the number of glomeruli in action, whereas in mammals the glomerular activity remains relatively constant, and diuresis is under predominant pituitary control.

The work for which Richards and Wearn are best known developed from their micro technique for the cannulation of amphibian renal tubules. Chemical study of the tubular contents established basic data on sites of tubular action on specific constituents of the glomerular filtrate. But the nature of the experiments did not allow of differentiation between tubular reabsorption and secretion. E. K. Marshall soon provided evidence that phenol red and urea were treated differently by the renal tubules, for whereas a rise in plasma urea concentration was associated with a parallel rise in urinary urea elimination a plasma elevation of phenol red was associated with a steep rise in urinary phenol red and then a flattening off to an asymptotic value. Such a result could not be explained on the basis of ultrafiltration alone. Furthermore phenol red was concentrated in the renal cortex even when the blood pressure was too low for appreciable filtration to occur. In any case some 80%

of the phenol red was bound to plasma protein and therefore not filtrable. Marshall and Graßlin's work on the toadfish's aglomerular kidney, which is fed only by venous blood, proved finally that tubular secretion does occur. Richards's rejoinder was to confront Marshall on having found an animal to confirm his theory.

Another great advance, the era of clearance studies was initiated independently by Richards and Sherrin, both of whom selected inulin as an inert, not too readily diffusible, substance which would traverse the glomerular filter and not be reabsorbed. Though inulin clearance a better index of glomerular filtration rate in the dog than in man, it still has a wide usefulness in renal research. Sherrin's work on the threshold for tubular reabsorption of glucose was the forerunner of subsequent studies on the maximal tubular reabsorption of T_m of such substances as ascorbic acid, sulphate, phosphate, uric acid, ketone bodies, and the amino acids. Urea was found to be an unusual compound in that it is passively reabsorbed with most of the water in the glomerular filtrate. The theory of ultrafiltration with its necessary corollary of reabsorption, involving concentration of the reabsorbed material against a gradient, and thus means that work must be done. The capacity of the renal tubule cells to do so much work in a given time is limited, and thus restricts the kidney's power of reabsorption. Clearance studies of substances which are actively secreted by the tubules give an indication of tubular mass when the plasma levels are high, and of renal blood flow when they are sufficiently low for the material to be virtually completely cleared from the blood in one circuit through the kidney. 'Diodrast' (diodone) and *p*-aminohippurate (P.A.H.) are the two substances most suited to this purpose. They both give the same extraction ratios in dog and man, and in eight different laboratories this figure for man is 0.914—i.e., 91.4% of diodone or P.A.H. is cleared from the blood on traversing the kidney once. The remaining 8.6% is probably attributable to the small amount of blood which reaches only those parts of the kidney not concerned with the process of urine formation.

Clearance studies on man have given results which would probably have seemed incredible to Cushny, whose ideas they so largely vindicate. Thus some 1200 ml blood (15–20% of the cardiac output) passes through the human kidneys each minute. As plasma this represents about 700 ml, and 130 ml of this is ultrafiltered through the glomeruli—i.e., 18 litres of glomerular filtrate is formed per day. Contained in this 18 litres is 1200 g NaCl, 400 g NaHCO_3 , and 200 g glucose, yet the amounts actually passed in the urine are only about 0.8 g, 0.2 g, and 0.1 g respectively. The accurate control of the body's electrolyte and water content is a most important kidney function, and depends on the maintenance of the correct renal blood flow, but the means by which this flow is regulated are still very imperfectly understood. The next chapter in research in renal physiology, Dr Smith said, is likely to be concerned mainly with the glomerulo-tubular balance for this is surely the key to the precise workings of the whole organ.

In man the glomerular filtration rate is relatively stable, but in the dog and especially the rat it is less so. On the tubular side it appears that in the proximal part there is a large obligatory reabsorption of water and salt constituting in man about 85% of the water in the glomerular filtrate, and that only the remaining 15% of the water is facultatively reabsorbed in the distal part of the tubule. Walker and Oliver in their punctate experiments on rat kidneys showed that 50–80% of the NaCl is reabsorbed in the proximal tubules, and the

BRITISH MEDICAL ASSOCIATION

the official religious service, held in Liverpool Cathedral on July 18, a large congregation heard the Rev. Canon of Birmingham declare that, after four centuries, the post Renaissance era was drawing to a close. In this phase that was now opening the outlook would be bright, and would be profoundly influenced by the advances in scientific knowledge. As to progress in medicine: "It is already clear that possibly the most important medical research of the future will be concerned with the elimination from human stocks of genetic defects, and with the production of human beings finer than any that have hitherto appeared. It is among such human types that the finer kinds of religious ethics will, in ages to come, show themselves." The increasing importance of medical science was already evident. "New knowledge is likely to bring ethical and religious changes which will be more significant than material progress. Among the consequences of an over-civilized world are starvation and warfare. Medical science, in many ways so valuable to humanity, is not without some responsibility for both calamities." The Bishop went on to express his disbelief in materialism. The two fundamentals, he said, were not mind and matter but mind and conduct.

At the annual dinner on July 20, attended by some 550 guests, Lord HODGER spoke of Liverpool as the gateway of the west, the focal point of the Battle of the Atlantic, and a city unique in having two cathedrals built in the 20th century. In medicine it had taken a lead especially in public health, in tropical medicine, and in orthopaedics. Responding the Lord Mayor (the Rev. H. D. Longbottom) said that, for all its slums and dark patches, Liverpool was a city of variety and charm, and the Vice-Chancellor (Mr. J. F. Mountford) mentioned that among the university's priorities the new medical school had almost the highest place. Prof. D. R. SEABORNE DAVIES, proposing The B.M.A., said that justice was the supreme good, "and justice for the patient was unattainable without justice for the doctor." Applying as chairman of council Dr. E. A. GREGG said that though the B.M.A. existed partly to advance the interests of those who practised medicine, a great proportion of its energies was devoted to improving the practice of medicine. "I would have preferred to see the National Health Service introduced in stages, but, now that the service was here, members of the profession must do nothing that would

enable anyone to point a finger of scorn at them. All must realise, however, that warfare for health against disease was, like other warfare, expensive, and there must be no stinting of resources." He spoke particularly of the needs of the public health service. Sir HARTLEY SHAWCROSS M.P., proposing *The President*, referred to Sir Henry Cohen's accession to the Chair of Medicine at 34 and of his long and untiring public service. All three political parties had sought his advice and it had been given objectively. In his reply Sir Henry COHEN took the opportunity to pay tribute to all those who had made the meeting a success. In dealing with the toast of The Guests, on which he had produced a 93 page preliminary memorandum, Mr. BRIAN MCFARLAND said there were those who thought that a dead hand had been laid on medicine and that its spirit was like to die. But the profession had remained free and faithful through worse trials than the present and its voice would rise again triumphant and clear. Lieut. Colonel R. FLEETWOOD HESKETH (Mayor of Southport), Dr. A. J. ORENSTED (South Africa), and Dr. DAG KNUTSON (Sweden) responded.

Among the films shown at the meeting were the following:

Treatment of Infections of the Hand—This new film, illustrating the practice at the hand clinic of the surgical unit, University College Hospital, London, was sponsored by Glaxo Laboratories Ltd., and produced by the Realist Film Unit Ltd. under the auspices of the British Medical Association. In sound and colour, it depicts clearly treatment that can be carried out single handed, and the need for choosing the right moment for surgical intervention is properly emphasised. The value of the film is enhanced by the summary with which it ends (116 mm., running time 28 minutes).

Total Sympathectomy for Hypertension—In sympathectomy operations, few onlookers can hope to see what the surgeon is about, because of the depth at which he is working. Thus this film, by Mr. A. Dickson Wright, which illustrates the procedure by the retropleural approach, should prove very popular. For, thanks to efficient illumination, even the deepest planes are clearly shown (16 mm., silent and colour running time 15 minutes).

In his public lecture at the close of the meeting, Dr. C. O. STALLIBRASS called for a national effort to eradicate tuberculosis. "And in this I know," he added, "that I represent the views of many, heavily disheartened and overworked, of those engaged in tuberculosis preventive work."

Scientific Sections

MEDICINE

President Prof. E. N. CHAMBERLAIN

Modern Conceptions and Therapeutics of Cardiac Failure—Prof. E. P. SHARPEY SCHAFER spoke of the need for a satisfactory definition of heart failure. To define it as failure of the heart to pump in a proper manner could embrace other conditions not commonly accepted as heart failure, and it overlooked complex alterations in the pressure/flow relations occurring in the peripheral vessels. The vascular response of the normal subject to changing from the recumbent to the erect posture consisted in vasoconstriction, elevation of the arterial blood pressure, and diminished peripheral blood flow. In contrast the patient with cardiac failure developed these changes when he passed in the reverse direction from the semi erect to the recumbent position. Elevation of the venous pressure was the important factor precipitating an attack of acute left ventricular failure, which was associated with intense vasoconstriction, raised arterial pressure, greater cardiac work, and dyspnoea. Vasoconstriction and dyspnoea produced further venous pressure rise, completing a vicious circle which could be broken by treatment designed to lower the venous pressure. It was tentatively suggested that these changes resulted from modification of the normal postural and haemorrhagic reactions.

Dr. RICHARD BAYLISS said that pulmonary hypertension occurred in less than half the cases of emphysema and mitral stenosis. In the patient with emphysema, pulmonary hypertension, and right ventricular failure, oxygen therapy would lower the pulmonary arterial pressure. It was not yet determined whether this effect was due to vasodilatation or to a fall in the cardiac output. It was uncertain what part pulmonary arterio-sclerosis played in the maintenance of raised pulmonary arterial pressure in patients with a severe degree of mitral stenosis. The answer could only be obtained by observing the results in patients with this condition who underwent valvulotomy.

Dr. PAUL WOOD was provocative in his remarks on raised venous pressure, which, he said, could and did exist without precipitating cardiac failure. He instanced, among other examples, the "high output states" associated with anaemia and thyrotoxicosis, in which it was often difficult to tell when patients passed into cardiac failure. He denied emphatically that digitalis exerted its effects by lowering venous pressure, and he illustrated absence of this action in a series of patients with raised venous pressure and high cardiac output but without heart failure. Postural treatment was vital and many more cardiac beds should be available. A low-sodium diet had been devised containing less than 1 g.

will be generally accepted. But it is not the complete answer to the question whether the radium beam has special advantages as a therapeutic instrument. Before forming an opinion on this question several striking findings in the report should be considered.

The detailed statistical tables show that at least eighteen patients with palpable lymph glands, seven of whom were treated with the X ray beam, were symptom-free for 3 years or longer. Cure of malignant glands by radiotherapy is rare enough to make this a considerable achievement, and the report points out that the usual view that secondary cancer in glands is more resistant and responds more slowly to radiation than the primary tumour was not borne out in this series, in which the glands often disappeared first. This suggests a special place for the radium beam, or even for an X ray beam of this type, in the treatment of cases where cancer in a difficult site, accompanied by palpable lymph glands makes block dissection of the neck almost impossible.

The effect of the two types of radiation on the skin is also important. It was found that the cases treated with X rays developed skin reactions earlier and more severely, so a further comparison was arranged between asymmetrical fields on the two sides of the neck of patients with suitable lesions, the fields on one side being treated with gamma rays and those on the other with X rays. This experiment showed that the average ratio of gamma ray dose to X ray dose for the same visible skin reaction was 1.34:1. Thus gamma radiation has a definite advantage, even if this is due to differences in penetration and absorption and not to any specific wave length effect. There is thus some evidence that beam therapy has special uses and that, even if the experimental X ray beam was a practical instrument, beam therapy should be given by means of gamma rays.

In the radium beam we have a source of radiation with which the block of tissue which contains the tumour can be raised to the required dosage, and which, if the tumour is superficial enough, gives a rapid fall in dosage outside this block, thus increasing the tolerance of the normal tissues. Analysis of the results of treatment by site indicates the sites in which conditions are favourable for radium beam treatment. Unfortunately, however, in some sites, particularly the pharynx, this method, in common with all others, results in so few survivals that no conclusions can be drawn from the figures. For lesions at the back of the mouth, and for some laryngeal lesions, more particularly when the lymph glands are involved, provisions for radium-beam therapy should certainly be made. The report says "Such apparatus" [the 10 gramme bomb] "may continue to be used in routine treatment for some time to come", it might have gone further and expressed the belief that some form of beam therapy, with either radium or radioactive cobalt, will continue to be used so long as irradiation is chosen for the treatment of oral cancer.

SIR HERBERT BARKER

Few undervalued practitioners in medicine reach the eminence attained by Sir Herbert Barker. His death at the age of 81 ends a career that roused strong feeling in the medical profession and brought controversy to a focus. The son of a solicitor, he became, at 19, assistant to his cousin, John Atkinson, who derived his knowledge of bonesetting, by a sort of apostolic succession, from the Hutton family, yeoman farmers of the North. Starting for himself in practice in Manchester, he found many patients among footballers and athletes, and won the confidence of Walter Whitehead, professor of clinical surgery in Manchester University. A first attempt to start a practice in London was abortive, but after a period in Glasgow he returned and had great success

A most skilful and intelligent manipulator, he sometimes succeeded where qualified practitioners had failed, and a number of doctors encouraged their patients to go to him—or went to him themselves. On the other hand the profession, as such, can never agree that persons who have not had a basic medical training can properly be entrusted with the full care of a patient, and the ultimate responsibility must rest on someone trained in comprehensive diagnosis rather than in a therapeutic technique. Professional opposition, carried rather too far, prevented any official use of Barker's services in the treatment of injuries during the 1914-18 war, and only the General Medical Council to remove the name of anæsthetist, Dr F. W. Axham, from the Medical Register for the offence of "covering" an unregistered practitioner. The case of Dr Axham was long and bitterly debated; the public thought it a monstrous example of professional obscurantism, and a sense of discomfort within the profession would have led to the restoration of Axham's name had he not died first, in 1926. Meanwhile the knighthood conferred on Barker in 1922, and the demand that he should receive a Lambeth M.D., reflected the public respect for his abilities, and more and more doctors were prepared to believe that a man with so much practical experience, and art, might have knowledge, or at least dodges, which could usefully be embodied in orthodox practice. In 1936 the British Orthopædic Association accepted his offer of a demonstration, and a report by Mr W. Rowley Bristow, published in our columns² describes how Sir Herbert Barker treated 18 patients at St Thomas's, where films were later made of his techniques.

"He taught," Mr Bristow wrote, "the value of repeated manipulation, the value of traction, the personal supervision and attention to exercising the joint in all directions afterwards, and above all to think, the splendid optimism which is essentially a part of treatment, and a necessary part, in helping the patient with long standing disabilities, whose confidence has been rudely shaken by failures of the earlier efforts at cure. It is due to Barker to say that but for his pioneer work in the manipulative field of orthopædic surgery would we occupy the position it does today, and that had his offer to demonstrate his technique been accepted twenty-five years ago the general utilisation of this branch of therapeutics would not have been so long delayed."

But though Barker did not quite realise it (Mr Bristow thought) the battle was already won. "Orthopædic surgeons now practise manipulative surgery as an essential part of their speciality."

INTERNATIONAL CONGRESSES

LAST Monday the sixth International Congress of Radiology, which is being held in London under the presidency of Dr Ralston Paterson, was rung in by six strokes on a silver bell presented by British radiologists to mark the silver jubilee of these international meetings. Afterwards the Earl of Athlone formally opened the proceedings, and Sir Henry Dale welcomed 2700 delegates from 54 countries on behalf of British science and medicine and on behalf of the Government. At the dinner held at Guildhall on Monday evening the toast of the congress was proposed by Lord Mountbatten. The exhibition of apparatus which is being held in connection with the congress shows the outstanding advances made since the last exhibition in 1937.

Meanwhile at Oxford, Lord Addison, himself a former professor of anatomy, welcomed 550 delegates from 25 countries to the international anatomical congress which is meeting there this week under the presidency of Prof W. E. Le Gros Clark, F.R.S.

ON July 22 Prof HILDA LLOYD was re-elected president of the Royal College of Obstetricians and Gynaecologists.

chances associated with fenestration operations, and lation sickness

min B₁.

J F WILKINSON outlined our limited knowledge of the chemical constitution of vitamin B₁₂ and the recommended scheme of dosage. Following an initial dose of 60 microgrammes, a weekly dose of 40 µg could be continued until the blood count was normal, which a weekly or fortnightly dose of 20-40 µg could maintain a normal blood count.

Dr DOUGLAS RIDING said that a non-dialysable inhibitor substance was present in the gastric juice of the normal human being, but not of the patient with pernicious anaemia, which combined with vitamin B₁₂ to form a compound in which the vitamin B₁₂ was no longer available for bacterial metabolism, but from which might be recovered by heating. He suggested that the inhibitor substance was the intrinsic factor of the ileum and served the purpose of rendering vitamin B₁₂ available to bacteria in the alimentary tract and before available for absorption, and that vitamin B₁₂ was the extrinsic factor.

Typical pneumonia was discussed jointly with the question of pathology and bacteriology (see below).

SURGERY

President Mr J BAGOT OLDHAM

Varicose Ulceration

Dr GUNNAR BAUER, of Mariestad, Sweden, began by giving his immediate results with popliteal venous ligation for postphlebotic syndrome of the leg. He has operated on 245 patients, and in almost all of them the "bursting" calf pain and leg oedema has been relieved. 196 followed for over six months, 16% had recurrent ulceration, but two thirds of these (i.e., 18 cases) have healed after ablation of the overlooked incompetent superficial veins, and most of the remainder, who showed some arterial insufficiency, have healed after ganglionectomy.

Prof A M BOYD emphasised the magnitude of the problem and the need for an organised campaign to deal with the large number of cases. He described the three common types of ulceration: those due to uncomplicated superficial varicosities, those following phlebitis, and those of arteriosclerotic (or hypertensive) origin, some degree of arteriosclerosis often complicating the second type. Turning to treatment, after pointing out the dangers of retrograde injection into the great saphenous stem at the groin, he spoke mainly about phlebotic ulcers. After carefully evaluating the factors involved, moving sloughs with eusol, controlling infection with cal streptomycin (1 g per litre), and reducing any swelling by elevating the limb on a wedge mattress, his practice is to excise the ulcer's fibrotic base and apply a skin graft. Venous stasis is controlled, and a major ganglionectomy performed in cases with associated arterial insufficiency, the first lumbar ganglion being always excised to denervate the medial side of the leg. This not only improves skin nutrition but abolishes sweating and thereby lessens the liability to relapse.

Mr A. C. BREWER was interested in the possibility of removing venous shunts by passing the capillary bed in series of phlebotic syndrome, and sought to demonstrate them by means of "timed" arteriograms. Dr S D CAUSLAND showed a coloured film, illustrating the conservative measures he has long used and advised continuous support after healing. Mr MAURICE LEE, also with the help of a film, described a skin grafting technique suitable for outpatients. Strips of full thickness 5 mm wide and freed of fat are darned in and out the ulcer granulations after these have been sterilised by local applications. This method has led to rapid healing.

Mr A. J. WALKER reported his initial results with popliteal venous section in 30 cases of postphlebotic syndrome, here also the bursting calf pain, local ulcer pain, and nocturnal cramps have been relieved. He has measured the venous pressures at rest and on exercise in the dorsal veins of the foot. In patients showing a rise of pressure on exercise, results have been poor, and this finding may prove to be a contra indication to the operation.

Mr A. DICKSON WRIGHT pointed out that most cases of leg ulceration occur in obese working class women in late middle age, and he was loath to advise major procedures which were not yet well established.

THE CHAIRMAN said that the crux of the problem lay in the elucidation of the vascular pathology. He drew attention to the frequent violent eczematous reactions to penicillin and sulphonamide creams applied to leg ulcers and asked the opening speakers to define the clinical indications for the operative techniques described.

In reply, Professor BOYD laid stress on the need for continued personal supervision. The patients are supplied with an elastic stocking, the 4 in × 12 yd 'Latex' bandage, which in his view is far superior, being difficult to obtain. No one treatment is suitable for all cases and each must be dealt with on its merits. In diagnosis if an Esmarch bandage is applied to a phlebotic leg it gives rise to great pain on exercise, whereas it produces no pain in a simple varicose leg. He agreed that, the measurement of venous pressures, arteriography, and venography are research investigations. Dr BAUER then described the method of venography and measurement of popliteal venous pressure during operation which he uses to detect incompetent valves. He keeps his patients in hospital as a rule until their ulcers have healed and then supplies them with a supporting bandage.

Burns

Mr R. P. OSBORNE urged the need to lower the high incidence of burns and for more burns units. The first-aid treatment consists in covering the burnt area with the cleanest material available and giving hot sweet drinks. The plenary treatment includes that of shock, plasma loss should be limited by elevation of the part, if possible the application of pressure dressings, and the administration of plasma, controlled by frequent haematocrit readings. Anaemia always develops in burns of over 8% of the body surface and anticipatory transfusion is essential. This should be combined with high protein and vitamin therapy. In the theatre, after cleaning with 1% 'Cetavlon,' he uses either penicillin cream applications or the Bunyan Stannard envelope technique. Unless the initial dressing works loose, or becomes saturated with plasma, or the patient's temperature rises, the dressing is not disturbed for 10-14 days. Early separation of sloughs is encouraged by the envelope method of irrigation with 'Milton,' &c., to permit skin grafting. Small full thickness burns can be dealt with by immediate excision of slough and grafting, otherwise this is done when the granulations are firm, flat, and free from haemolytic streptococci.

Mr J. P. REIDY said that early grafting reduces toxæmia and produces rapid healing and restored function. Grafts of split skin, 1/2 in square, are most economical and satisfactory. Pinch grafts are never indicated, though full thickness grafts and skin flaps are useful when healing has been achieved. Homogenous grafts are used as a temporary measure to aid in covering a very large area until the patient can provide more skin for himself. The failure of grafts to take may be caused by the patient's poor general condition, or by inadequate skin graft fixation and unhealthy granulations, though the presence of a few organisms does not absolutely contra indicate grafting. The covering of one part of the burn must not be delayed because another is

of sodium per day, and a patient on this diet did not require more than two or three injections of a mercurial diuretic at the beginning of treatment.

Dr WILLIAM EVANS thought that there was too much experimental investigation of the already overburdened heart. Observation of the clinical condition of the patient and of his response to therapy provided all necessary information for the purposes of treatment and prognosis. Rapid digitalisation could be achieved when necessary by administering 2.5 mg digoxin orally, but the patient should be maintained on digitalis leaf, its use should not be limited to auricular fibrillation, for it was of value in sinus rhythm, right ventricular failure due to emphysema, and myocardial infarction. He had not seen paroxysmal ventricular fibrillation which could be attributed to digitalis in myocardial infarction.

Ulcerative Colitis

Prof T L HARDY, introducing this subject at a joint meeting of the section with the section of surgery, emphasised our ignorance of its aetiology. Micro organisms were only present in the rôle of secondary invaders of the ulcerated bowel. Among psychological factors, immaturity of outlook and parental attachment had been stressed, but these appeared to be non specific in nature and were often seen in control series. There was evidence that emotion, through impulses mediated by the vagus, could produce alteration in the state of motility of the colon: stimulation of the sacral autonomic outflow had produced overactivity, engorgement, and ulceration. The protective action of mucus was well established, and the finding of excessive quantities of the mucolytic enzyme, lysozyme, in the stools of sufferers from ulcerative colitis suggested that this might be a possible aetiological factor, but recent work had shown it was more likely to be derived from and associated with the pus in the stools. Three patients had been treated with adrenocorticotrophic hormone with resulting symptomatic remission, but the rectal mucosa remained abnormal. It was too early to express an opinion on the usefulness of chloramphenicol and 'Aureomycin,' but results encouraged further trial although the mucosa had never been seen to return to normal, the drugs only reducing the secondary invading organisms. Ileostomy was advised more and more frequently in selected cases.

Mr A HEDLEY WHITE said that he was pleased to note the agreement which existed between the physician and surgeon about treatment in the chronic and relapsing types of ulcerative colitis. Ileostomy was the treatment of choice except in the acute fulminating case, which required resuscitation as an emergency measure. Ileostomy did not cure the condition, which, in a proportion of cases variously estimated at 2 to 10%, would continue to progress and lead to the development of pseudopolypoid colitis and carcinoma. Colectomy should therefore follow ileostomy.

Dr J W PAULEY gave an interesting account of his psychological investigation and treatment of 173 patients with ulcerative colitis. In addition to the prominence of mother dependence, disturbed emotional relations in the home were notably common. Financial stress or frustration played no part. As a group, the patients lacked aggressiveness and preferred to avoid domestic quarrels but they would harbour a smouldering resentment with the air of martyrdom, brooding over real or imaginary wrongs. They were querulous and ungrateful. The men were effeminate, and both sexes were neat and fastidious, exhibiting false modesty and a poor sense of humour. Therapy was time consuming and was directed initially towards transferring possession from the mother to the therapist, who could then encourage the patient to acquire self dependence. Improvement had been obtained and maintained without the need for surgical intervention.

Mr HAROLD EDWARDS advised an elective three-leostomy and colectomy, for other operations liable to produce complications later, particularly intestinal obstruction. With the advent of the antibiotics, appendicostomy and continuous drainage would be worth a trial.

Mr J A SHEPHERD described the advantages of "spout" ileostomy over the more usual flange, and Mr DICKSON WRIGHT emphasised the importance of early operation in the patient with segmental colitis where anastomosis was possible, with complete removal of the affected segment of colon.

Anti histamine Compounds

Prof J H BURN, F.R.S., opened the discussion by describing experiments begun in 1945 to discover an effective substitute for quinine. Local anaesthetics, spasmolytics of the belladonna group, pelludine, and 'Neontergan' ('Anthusan') were found to have quinine-like action. Neontergan also possessed anaesthetic and analgesic effects. Dutter confirmed these findings, extended them to other members of the anti histamine group, and demonstrated their effect reducing the action of acetylcholine on the skeletal muscle of the frog and the rat, and their ability to block impulses in perfused ganglia. Thus the anti histamine group of drugs possessed many of the properties of quinine in this respect resembled more familiar substances and it could be predicted that side effects, such as dryness of the mouth and mental confusion, would inevitably ensue from their use. As 'Benadryl' and hyoscine were closely related in their action, and hyoscine, in his opinion, was the best available seasickness remedy, it was not surprising that Dr Gay had found 'Dramamine'—which was only benadryl with an added theophylline grouping—an effective remedy in this condition, but Professor Burn had seen no evidence that it was more effective than hyoscine. Benadryl and anthusan were useful in the treatment of myotonia, in which condition quinine has long been known to bring relief, and they might find a place in the treatment of fibrillation in view of their quinine-like action.

Prof D M DUNLOP considered the therapeutic use of the anti histamine drugs, and recounted the results of his experience with anthusan, benadryl, and 'Phenergan'. Sleepiness and nausea were the most important side effects and occurred rather more frequently with benadryl. Dizziness, vomiting, and diarrhoea, though occurring frequently, were rather more marked after anthusan. Altogether, toxic effects were seen in over 60% of cases treated with benadryl and in 55% with anthusan. An allergic oedema and urticaria in more than 80% of cases and hay fever in more than half the cases, responded well to anti histamine therapy. Perennial vasomotor rhinitis also responded, but similar success was achieved by employing inert tablets, and in the treatment of asthma inert tablets had caused a slightly greater decrease in the incidence of attacks than had anthusan.

Dr LESLIE GAY (Baltimore) presented a detailed account of the large scale trials of dramamine in the prevention and treatment of motion sickness, conducted by him in the U.S. army and navy, and various American airlines. He said that dramamine was a most potent prophylactic and therapeutic agent in this condition, and though it was true that no comparative studies using dramamine and hyoscine had been undertaken he could not agree with Professor Burn that such a study was necessary. He was satisfied that the latter drug could not be used in the frequency and over the length of time necessary to provide effective control. His experience in the U.S. States, where car and train sickness appeared to be a more important problem than in this country, convinced him of the benefit obtainable from dramamine. Dramamine was effective in the treatment of labyrinthine

thought that there was a tendency to aim at too high a standard in selection of personnel and that only obviously unsuitable should be discarded. The point to which history taking should be delegated to social worker was discussed.

THE PRESIDENT mentioned the growing practice of making the social worker to be the receptionist. He said that, as the psychiatrist is primarily a physician, should take personal responsibility for getting the story and carrying out a skilled examination, calling the social worker for assistance at a later stage. It was generally agreed that it was unwise for the psychiatrist to treat both the child and the parent, but opinions were divided about where to draw lines between the roles of social worker as an adviser, a teacher, and a therapist. Miss K. M. LEWIS, who had been nominated as a representative by the Association of Psychiatric Social Workers, referred to the mutual trust that lies at the basis of all team work, and Miss E. THOMAS, another representative of the association spoke of herself as a "social" psychiatric social worker and the approach to human relationships as "an art rather than a skill." The danger of concentrating too much attention on the child and too little on the total family and social situation was mentioned by another member of the association.

The meeting of the section ended with an exhibition and demonstration of *modern techniques in child psychiatry* held on the premises of one of the first psychiatric inpatient clinics to be established in this country. The contributions ranged from the newer psychodiagnostic techniques to the puppet theatre shown by Dr H. S. REAN, and included an exhibit of psychiatric interest on the Moor House School of Speech Therapy. The laudley Hospital sent a comprehensive display of educational value, comprising the organisation and equipment of a modern child psychiatric unit, amply illustrated by diagrammatic and clinical productions. Serial drawings by child patients under treatment were shown by the staff of Crichton Royal. The progress of electroencephalography as applied to children provided the topic for several exhibits, and Dr S. S. HODGE, Dr F. H. BODMAN, and their team of technicians armed with a galaxy of electrical equipment gave an impressive demonstration of some recent developments in photic stimulation. Diagnostic measures were more in evidence than therapeutic procedures, but there were encouraging signs of centres in the country where established methods of treatment are being refined and new techniques devised and their results scientifically recorded.

TROPICAL MEDICINE

President Prof R. M. GORDON

Parasitology in Relation to Dermatology

At a joint meeting with the section of dermatology, Dr R. M. B. MACKENZIE recalled that about a century ago there occurred in Liverpool a grave outbreak of epidemic typhus imported in refugees from the Irish potato famine. The mode of transmission was not known, but as conditions of destitution and vermin infestation were associated with the infection the authorities built disinfecting stations and public wash-houses, and typhus declined. A second epidemic followed some twenty years later, as a result of the American Civil War and consequent failure of the cotton trade. During the late war infestation with the head-louse was common in women joining the A.T.S., particularly among those from industrial areas, and children from the urban areas were also heavily infested. Methane gas, D.D.T., and so forth were used to reduce head louse infestation as the possibility of typhus was considerable at that time. Owing to the susceptibility of the head louse to changes in temperature and humidity, males with short hair were rarely infected.

Diagnosis of a minor infestation with scabies in a cleanly person was difficult, and scabies infestation had been reduced by the use of 'Tetnosol' soaps. A first infestation with scabies did not cause discomfort or gross signs for at least a month, but the patient then became sensitised and the diagnosis became clinically obvious. If cured and reinfected, the patient immediately showed clinical signs. Cat scabies infection was more prevalent in man than was realised. Two parasites were involved—*notedres* and *cheyletiella*, neither persisted long on the human, and the infections vanished when the offending cat was removed or treated. New cats might become infected from the rodent population and reinfest man. Pubic louse infestation, in which the eggs were small and dark and were attached to the hairs close to the skin, was commonly missed, particularly in women. Insect bites were said to be more severe in those deficient in vitamin B₁, administration of this vitamin was reputed both to reduce the effect of the bites and to lessen the number of bites, but this was open to question.

Prof R. M. GORDON discussed reactions in the human skin directly due to arthropods. These reactions might be classified into four types due to (1) mechanical trauma, (2) secondary bacterial infection, (3) injection of substances to which the host had become sensitised, or (4) injection of irritant substances. To the first group belonged the bites of any blood sucking arthropod, the nature of the lesions depending on the mechanism of biting. Bacterial infection of wounds caused by arthropods was no more likely than with wounds caused by other agents. A severe reaction to the bite of an arthropod was due to specific sensitisation to the bites of that particular arthropod. The venomous offensive or defensive weapons of bees, scorpions, or spiders caused changes ranging from severe inflammation to extensive coagulative necrosis.

Dr J. E. NAPIER stated that the skin cases encountered in Calcutta approximated to those seen in temperate zones. Only a small proportion were due to local diseases; among these, cutaneous leishmaniasis was prominent. Two types of cutaneous leishmaniasis were seen in India—a true cutaneous leishmaniasis, or oriental sore, due to *Leishmania tropica* occurred principally in the North West and post kala azar dermal leishmaniasis was found in the Bengal area following about a year after apparently successful treatment or spontaneous cure of kala azar. It was very doubtful whether regeneration of the systemic infection in the form of kala azar resulted from the latter.

Dr JOSEPH CAPLAN gave an account of dermal lesions in strongyloidiasis. When he published his original account he thought this condition was confined to ex-prisoners of war from the East, but he had since seen it in people who had not been in these camps. Strongyloides creeping eruptions were of two types: in one the tracks were narrow, while in the other they were about 1/4 in wide. Extension of the tracks was much more rapid than with a classical creeping eruption. In the United Kingdom lesions had appeared some five years after infection, anatomically they might be extensive, and they were accompanied by an eosinophilia of from 10 to 25%.

Dr D. G. FRESHWATER described skin lesions in cases of onchocerciasis in West Africa, and suggested that none of these lesions, other than the nodules, were characteristic.

Intestinal Parasites of Man in Great Britain

Prof J. J. C. BUCKLEY said that about a dozen species of worms had been recorded in man in Britain, of which only half could be regarded as normal parasites, the others being present owing to accidental infection from domestic animals. Of the commoner nematodes, four occurred here—the roundworm, the whipworm, the

not quite ready. He has used preoperative and post operative X irradiation to control keloid formation.

Mr A B WALLACE emphasised the importance of controlled fluid replacement, incipient oligemic shock is heralded by pallor, thirst, and restlessness. He showed a chart which he uses as a guide to the intravenous therapy which is always necessary for burns involving more than 12% of the body surface. Urinary excretion is an excellent guide to the adequacy of fluid therapy. With the aid of a coloured film, Mr Wallace then described his "dry" method of local treatment. The area is cleaned in the theatre with 1% contramide and thoroughly dried. Penicillin powder in lactose is insufflated over the area and this is left exposed to the air in the general ward. It is repowdered two hourly until a dry crust has formed—the best protection against infection. Both superficial and full thickness burns thus treated do not become infected despite heavy air contamination. When ready, the crust and slough are peeled off and the usual grafting measures employed.

Mr H M BAJTINGER, of Indiana, agreed largely with the first two speakers. He aims at a 4000–5000 calorie diet with up to 150 g of protein daily, and he transfuses patients to maintain their haemoglobin at over 85%.

Mr J A SHEPHERD preferred fresh blood to stored in these cases. Clinical assessment of fluid requirements is better, he thought, than any rule of thumb—a point contested by Mr R MURLEY, who has found it easy to go very wrong unless some formula is used as a guide. During a visit to Edinburgh, Mr Murley said, he was highly impressed by Mr Wallace's cases. In the Army, Mr R B WELBOURN said, he found that grafts would take even in the presence of a *Ps. pyocyanea* infection.

Replying, Mr REIDY said he also uses a chart to guide fluid replacement. Occasionally he has found a Blair or Humby knife useful in cutting grafts but the dermatome, he thought, is tedious and unnecessary. Mr OSBORNE again emphasised the inevitability of anaemia developing after a burn of over 8% of the body surface, and the need to control this and to prevent sepsis. Early skin grafting in his view is especially desirable to obtain a good result for the burnt hand.

Ulcerative colitis was discussed jointly with the section of medicine (see above), and renal failure with the section of pathology and bacteriology (see below).

PSYCHIATRY

President Sir DAVID HENDERSON

The Psychological Involvements of Childbearing

The divorce of psychiatry from neurology and the establishment on this occasion of a separate section, gave an opportunity to the psychiatrists which Dr EDWARD GLOVER was quick to seize. In opening the discussion he defined the relation between the two sciences of obstetrics and psychiatry, dealt with the contest between biological and psychological processes, and described normal childbearing in the face of powerful psychic inhibitions as representing the successful overcoming of the conflict. He stated that, as revealed by play and fantasy, the average child is much more interested in pregnancy and childbirth than the adult, and that as man is constitutionally a bisexual animal, the female of the species is prone to regress to infantile sterile positions.

He mentioned the clinical manifestations that may appear, including psychoneurotic anxiety states and character disorders, disturbances of menstruation and of the sexual functions, marital difficulties, psychogenic sterility, and the various psychogenic disorders of pregnancy such as pernicious vomiting and miscarriage. Turning to the practical application of his theories he believed that antenatal psychological care should begin in premarital life, and that it should take the form not merely of treatment aimed at freeing the woman from guilt feelings, but a positive education for pregnancy

beyond mere sexual information. He believed the "psycho obstetrician" of the future would not emerge from the case until weaning was complete.

Prof W I C MORRIS, giving the obstetrician's view, emphasised that the mother's attitude towards bearing a child was not always joyous, and might be in different pregnancies or in the course of a single pregnancy. He gave, as an example, shame at conception, or shame because there had been an interval between pregnancies—for instance when a previous child had reached adolescence. He spoke of the dangers of gossip and tittle-tattle in antenatal waiting rooms, of the psychological vulnerability of the primigravida, and of the need for building up the mother's prestige. He spoke of the mother's fears during the first stage of labour, her fighting attitude during the second stage, her sense of disappointment on finding the third stage that labour was not over, and the trials and sorrows of the puerperium. A sense of exaltation was apt to be followed by disillusionment, as the result of loss of freedom, change in economic circumstances, and the fact that babies are born "with a strange arrogant wickedness in them," became apparent to her. Considering the advantages of hospital as compared with domiciliary care, he decided that the scales were weighted towards confinement in the home.

Prof E W ANDERSON, in a closely argued statement on the significance of sexual maturity in women in the light of puerperal psychosis, added a note of erudition but the discussion was directed back to the human element by Dr ELIZABETH TYLDER's eloquent plea for more enlightenment and for the application of common educational principles to the subject. She was strongly critical of hospital practice and of the hard and punitive attitude of attendants, more particularly towards primiparae. Discussing the social setting, she explained that childbearing—and she spoke as a mother—was no longer the only goal to which woman can reach, and referred to the change from freedom to dependence, from companionship to loneliness, and the heavy responsibilities that resulted from childbearing. She stressed the need for giving mothers the opportunity to relieve themselves of their anxieties, and of helping them to understand the process of childbirth.

The discussion was informed and vigorous. The importance of the field on the preventive side, the dangers of attempting to educate people by means of literature, the need for permeating the community with better attitudes towards childbearing, the advantages of domiciliary midwifery put forward by a general practitioner, the idea of converting the hospital into a "home" to overcome the practical obstacles in the form of risk of infection, the power of unhappy married life in prejudicing a child against sex and marriage, the possibilities inherent in closer integration of child welfare and child guidance, and in group discussions in the antenatal clinic to overcome the dangers of "antenatal chatter" and spread of misinformation, were among the aspects discussed. The subject proved a meeting ground for those making different approaches, and set a standard of good feeling and toleration of the viewpoints of others.

The Role of the Psychiatric Social Worker

Dr J B S LEWIS discussed the need for psychiatric social work, the field, and the acute problem of supply and demand, he suggested as immediate measures the employment of part time married workers, and the recruitment of men and of other clinical workers, and emphasised the importance of skilled selection of personnel. Psychiatrists, psychologists, and psychiatric social workers, he thought, should receive a basic training, it were, from the cradle. Later speakers confirmed the importance of group training in outpatient departments and of close co-operation, frequent meetings, and discussion between the various members of the team.

Dr F I PRIME discussed bronchiectasis from a physiological point of view. It causes, he said uneven ventilation of the lung resulting in arterial suboxygenation. Carbon dioxide content, however, is not usually raised unless some secondary condition is present such as severe emphysema. In examinations of bronchiectatic subjects he found that both the vital capacity and maximum breathing capacity were below normal. In the discussion which followed, several speakers pointed out that the term bronchiectasis was loosely used and made a plea for a more rigid classification. The section joined the section of otorhinolaryngology in a discussion of *Carcinoma of the Larynx* (see below).

OTORHINOLARYNGOLOGY

President - Mr I SIMSON HALL

Management of Carcinoma of the Larynx

It was refreshing and convincing at this joint meeting to hear at last such a wide measure of agreement between surgeons and radiotherapists on the management of patients suffering from carcinoma of the larynx. Mr P WILSON, Dr M LEDERMAN, Prof V LAMBERT and Dr J J STEVENSON opened the discussion in the use of which particular emphasis was placed upon the value of collaboration of the two specialties, particularly by joint consultation not only in deciding on the right kind of treatment to adopt but also in following the progress of each case. The day is long past when radiotherapy was regarded as a last hope to be employed only when surgery is impracticable or has failed. On the other hand long trials with radiotherapy alone have shown, it was agreed, that in early cases irradiation or total excision each offer an equal prospect of freedom from recurrence, whereas in more advanced cases, particularly when the growth has extended backwards or downwards, radical removal gives the best results. Advances in technique and its use as a curative rather than a palliative measure have greatly reduced the discomfort attending treatment by irradiation. Sulphonamides and antibiotics in combination with surgery, by lessening the incidence of postoperative infection have led to a shorter and smoother convalescence. For the same reason more extensive excisions can now be safely carried out on growths which formerly would have been considered inoperable, and which irradiation was unlikely to cure. When a growth is confined to the anterior end of one vocal cord a cure can be anticipated in more than three-quarters of the cases either by surgery or by irradiation. In such early cases, however, irradiation may often be preferred because it leaves the patient with a better voice. A growth extending forwards on to both vocal cords should be treated by irradiation. Any growth that extends backwards on to the arytenoid region of the larynx or downwards into the subglottic region, particularly if it has led to fixation of the cord, can be offered a better prospect of lasting cure by laryngectomy. In discussing doubtful cases speakers were in mind that whereas unsuccessful irradiation can sometimes be followed by a surgical cure a postoperative recurrence rarely responds to subsequent irradiation.

Deafness in Children

Mr R R SIMPSON, Mr J H OTTY, and Mr T S MITLER were the openers of a useful discussion. Permanent deafness in children, it was noted, can in many instances be prevented by prompt and appropriate attention directed towards the cause. In many urban areas—Hull and London were particularly mentioned—school medical services have schemes in operation for examining the ears and testing the hearing of all the pupils. Any child with defective hearing or diseased ears is referred to a special ear clinic for diagnosis and necessary treatment. These clinics are maintained by the local educational authority and are open during

school hours. The visits count as part of school attendance. Thus everything possible is done to encourage the pupil, parent, and teacher to coöperate, particularly when regular daily treatment over a period is needed. It is hoped that these centres will be allowed to continue their good work unhindered. Children permanently but not totally deafened should be given the opportunity to use a 'Medresco' hearing aid, supplied under the National Health Service. In one centre a fairly large group of partially deaf children was trained in the use of this aid and it was found that both they and their parents quickly appreciated its value. Moreover the teachers reported that all the children showed genuine pleasure in using an aid that their speech was improved and that they were much more alert mentally. There were no complaints from this group of children about the size and weight of the aid and the incidence of repairs was no greater than among aids used by adults. Another speaker reported that in a residential school for the deaf, a quarter of the children were found capable of benefiting by the use of aids and were supplied with them. It was generally felt that so long as the demand for medresco aids continues to exceed the supply, children should receive the first consideration.

OPHTHALMOLOGY

President - Mr A McKIE REID

Despite the counter attraction of the International Congress of Ophthalmology, the meeting of this section was exceptionally well attended.

Radiation Light and Illumination

Mr J N ALDINGTON, PhD, president of the Society of Illuminating Engineers, remarked that the eye had evolved through many ages under continuous radiation from the sun. The subjection of the eye to other sources of light might perhaps be thought to be associated with risks of damage, yet this had not proved to be so. Up to about 1930 almost all light sources gave continuous radiation, now the sodium lamp was the most efficient of all the general illuminations in use. Investigation had revealed no harmful radiation from fluorescent lamps. Dr Aldington went on to cite several examples of the close relationship between ophthalmic research, applied ophthalmology, and his own work on illumination.

Colour vision in the Central Forebrain—Great strides are being made in the study of colour-vision, and the processes of photo-reception and of the mechanism of vision itself are coming to be better understood. Since the publication of his book *Retinal Structure and Colour Vision* Mr E N WILLMER, SC.D., has continued his research work at Cambridge and at the meeting he reported some new observations on the colour vision of the central forebrain.

GERIATRICS

President - Dr C O STALLIBRASS

Care of the Aged

The most significant thing which emerged from the section of geriatrics was the agreement among general practitioners that since the arrival of the National Health Service it has been harder to get an elderly patient into hospital. Dr P Y LILE of Southport, found that two thirds of his visiting list was composed of patients over sixty-five. City practitioners such as Dr A FRANKLIN, of Liverpool, pointed out that this was chiefly an urban problem because there seemed to be many more idle, lonely and unwanted old people in the towns. Countrymen often continued with their accustomed work and play well into the seventies and eighties, thus avoiding the sudden break of passing from activity to lack of occupation on retirement from work. Many doctors thought that they were too busy to attend to their

threadworm, and *Trichinella spiralis*. Infestation with the beeftape worm—*Taenia saginata*—might be on the increase, since measly beef was now more prevalent than before the war: this was also the case in Denmark and elsewhere. The reasons were uncertain. The pork tapeworm—*T. sodium*—disappeared from this country with the introduction of proper meat inspection; infested pigs usually had very large numbers of cysts which were readily seen. The fish tapeworm had so far not been recorded indigenously in this country, though it occurred in Ireland.

Dr C A HOARE said that infection with *Entamoeba histolytica* involved a significant proportion (between 1 and 4 million) of the population of the British Isles, most infected persons did not suffer from clinical dysentery. *E. histolytica* could live either commensally or as a pathogen, but the reason why it changed its habits was not clear. There might be some non-pathogenic strains of *E. histolytica*, commonly associated with the production of small cysts. The few indigenous cases of frank amoebic dysentery were probably the result of infection with pathogenic strains introduced from overseas. Two great wars had not materially influenced the incidence of the infection in the British Isles. In view of the possibility of the commensally living parasites becoming pathogenic it seemed wise to treat this infection.

Dr E H VERE HODGE discussed the treatment of helminthiases in man. No anthelmintic was surely effective, and before such a drug was given concomitant infections should be corrected. In one case of strongyloidiasis, most encouraging results were obtained with methylene blue.

Mr R B GRIFFITHS said that until lately infection of beef with *Cysticercus bovis* was thought to be rare in this country, but in the past two years it had become evident that the condition was now prevalent. There was no real proof that *T. saginata* infection in man had materially increased. The recognition of gross infection of a carcass with *Cysticercus bovis* entailed the condemnation of the carcass. In light infections the beef was treated by freezing, in order to kill the cysticerci before the meat was issued for consumption. Infection from undetected light infection of beef could be avoided by cooking the meat. Housewives might be infected by swallowing cysticerci adhering to the hands when preparing beef for cooking, and this might account for the fact that in women infection was four or five times as common as in men.

Dr NAPIER said that in the U.S.A. the infection rate with *Trichinella spiralis* was higher than in this country. Light infections, which were not clinically obvious, might immunise against subsequent reinfection.

Dr R C MAC KEITH described an infection of the conjunctiva of a child with *Enterobius vermicularis*, and he mentioned instances of abnormal location of this parasite in the fallopian tubes and elsewhere.

Brigadier J S K BOYD said it had been established that in the recent Wolverhampton outbreak of trichinellosis uncooked meat in sausages was the source. He thought that giardia infections were not invariably harmless, but that they might cause diarrhoea. Tissue invasion by *E. histolytica* might be precipitated not only by recognised pathogenic bacilli, such as shigella, but by such organisms as *Bact. coli* which were not invariably pathogenic. Dr VERE HODGE was firmly of the opinion that giardia could give rise to diarrhoea in children.

Mr P L LE ROUX, D.Sc., discussed the helminthiases from the veterinary aspect, and stated that helminths might produce manifestations not solely by themselves but as agents for the introduction of various pathogenic bacteria. He thought that closer integration of human and veterinary medicine and of the public health authorities would be a powerful factor in controlling parasitic infestations.

Colonel W H HARGREAVES agreed that bacterial organisms could facilitate the invasion of tissue of *E. histolytica*, control of these organisms, antibiotics would lessen the invasive tendencies of protozoan parasite. Dr A R D ADAMS mentioned difficulties in the diagnosis of an *E. histolytica* infection. He was unable to differentiate between vegetative *E. histolytica* and vegetative *E. coli* on morphology. He regarded sigmoidoscopy as of no great value in the diagnosis of amoebiasis, since in mild attacks of amoebic dysentery no lesions might be seen, and he deplored the use of the so-called provocative emetine dosage, which had no justification either in theory or in practice.

RADIOLOGY

President Dr J S FULTON

Some Aspects of Bronchiectasis

Dr J C H MACKENZIE pointed out that there are no reported statistics of the incidence of bronchiectasis in the community and went on to quote figures from the Leicester Isolation Hospital and Chest Unit. This showed an incidence highest in children up to the age of 15—the greater proportion of them being females. The incidence in Leicester school children was 2.9 per 100, but communities differ according to social factors, the efficiency of isolation of tuberculous parents from children, and the efficiency of chemotherapeutics and antibiotics. The main aetiological factors are, he thought, either mechanical or infective. Congenital bronchiectases, though it may occur, is rare and so not important. He quoted Linder and Davidson's work showing the traction forces within a collapsed segment produced dilatation of the bronchi, and Linder's later work suggesting that, in an incomplete bronchial stenosis, the collapse is peripherally situated and the bronchi dilated, but that dilatation may also take place in complete obstruction, from secretory pressure.

Dr Mackenzie regarded infection as the main aetiological factor and discussed infections producing dilatation of the bronchi under the headings of acute, embaculate and chronic. Acute destruction of lung tissue is seen in Friedländer's pneumonia, non-specific suppurative pneumonia, and certain virus diseases associated with monitis, and secondary infection. Subacute destructive changes take place in tuberculosis, when the upper lobes are usually involved, but most cases of bronchiectasis are due to chronic infection and begin with atelectasis of the lower lobes either from an inflammatory cause or from glandular pressure, particularly tuberculous hilar adenitis.

Dr F WHITWELL said that in reviewing about 400 operation specimens of bronchiectatic lungs he found, broadly speaking, three pathological types.

The follicular type is seen in children, usually as a sequel to measles, whooping cough, or influenza, and is really a chronic interstitial pneumonic type. Microscopically, the bronchi are thickened, the alveoli become solid, and there is a surrounding chronic interstitial pneumonia. Fibrosis develops as a later stage following collapse.

The saccular type, in which the dilatation of the bronchi greater occurs in older patients and does not seem to be related to previous illness. It arises as a chronic mucous bronchitis in which the larger bronchioles become thickened, the smaller lateral bronchioles become obliterated, and the end result is an elongated sac which may become filled with mucus. This infection causes a dilatation and so the sacculus formed.

Atelectatic bronchiectasis occurs as a result of obstruction, usually due to hilar adenitis causing blockage of the main bronchus and so collapse of the lung. It is commonest on the right side and may revert to normal if the cause of the obstruction is removed. If there is fibrosis, bronchiectatic changes will develop.

Dr Whitwell found that nasal sinus infection is a common sign in the follicular and saccular types but rarely seen in the atelectatic bronchiectasis.

ie maximum resolution in relation to living tissues.

A. S. MCFARLANE said that with electron micro resolution was far greater than with any other at the limits being in the region of 5-10mμ. Dr. arlane referred to work on muscle structure, isozoa, the retinal rods and insect viruses illustrating remarks with a series of very fine lantern-slides.

at Pneumonia

a joint meeting with the section of medicine. C. H. STUART HARRIS described the subject of cal pneumonia as confused. Despite the apparent similarity of cases, the cases were clinically similar. 'Pneumonia' was sometimes effective, but its very use called for well-controlled clinical trials if a measure of value was to be obtained.

of S. P. BEDSON F.R.S. recalled that pneumonia was the first causative agent of the group to be considered. Severe cases of pneumonia were not at all atypical pneumonia, but mild cases were quite indistinguishable and pneumonia or ornithosis probably account for about 10-12% of all examples of the syndrome. A true diagnosis was essentially a laboratory problem, although ideally the virus should be isolated. In reality diagnosis depended upon complement-fixation tests. The antigen prepared from the virus was common to the LSV pneumonia group and consequently the test only group-specific results must therefore be interpreted in the light of the clinical findings. Absorption experiments had shown that a specific reaction could be aimed and the heterogeneous viruses excluded. Such methods, however, were not practicable for routine use. Professor Bedson referred to the use of skin tests in the diagnosis of infections of the pneumonia-ornithosis group. He presented results which suggested that such tests might have some practical value.

Dr THOMAS ANDERSON presented a series of cases which might have been labelled atypical pneumonia, which were shown on further investigation, to be examples of interlobar effusion, tuberculosis, or lung cancer. He suggested that too great readiness to run a case to the benign group of atypical pneumonias might result in more serious disease being overlooked.

Dr JANET NIVEN said that despite some broad similarities, the various types of human infection differed in each other in detail. In material from a fatal case of Q fever it had been possible to demonstrate bacteria both intracellularly and extracellularly.

Dr M. G. P. STOKER gave a short account of Q fever in Europe. In this disease due to a rickettsial infection, prognosis, as with pneumonia, depended upon the organism, a complement-fixation test being employed in the diagnosis of the causative agent was again the ideal but was not easily achieved. Cold agglutinins were not always present in high titre and the Weil-Felix reaction negative. In the United Kingdom Q fever was found in endemic foci in Kent, for instance, examination of sera from blood donors gave evidence of previous infection in 13 out of 50 whereas in a series of 200 sera from East Anglia no positive results were obtained. In endemic areas much of the raw milk could be shown to contain the causative organism.

renal Failure

Dr R. SHACKMAN, who referred particularly to post-operative renal failure affecting the normal kidney, said that local vasodilatation or constriction of the glomerular capillaries might play an important part in the response of the kidneys to unfavourable conditions. Severe renal failure left the patient in a condition almost equivalent to that after nephrectomy. If such a patient could be kept alive, the tubular cells regenerated. The regenerated cells resembled infantile ones in that they were incapable of effectively concentrating the glomerular filtrate.

Prof J. H. DISLE showed a series of slides illustrating the pathology of tubular damage in renal failure. In tubular failure the earliest changes were at present ill defined, since little material from such cases had been available for study. Broadly, the histological appearance in tubular necrosis could be classified according to the presence or absence of pigment. Such a division reflected the pathology, for example cases arising after intravascular hemolysis showed this pigmentation, whereas renal failure cases following surgical shock or severe burns did not.

Dr E. M. DARMADY said that despite the clinical and histological similarity of cases showing this syndrome, there were about seven possible aetiological groups into which they might fall. These were (1) surgical shock, (2) disturbance of water or electrolyte balance, (3) haemolysis, (4) allergy, (5) chemical nephrotoxins, (6) infection general or local, and (7) obstetric. When more than one of these causes was operative the prognosis was correspondingly poorer.

Dr G. M. BULL analysed 50 cases of acute tubular necrosis of varying aetiology with special reference to effective treatment. Renal failure of the tubular type showed four stages. First there was the onset, when the damage was initiated. Here the urine volume fell rapidly and the blood urea rose. This soon passed into the second phase of oliguria or anuria where tubular damage was maximal and renal blood flow was reduced. In the past most deaths in this phase had resulted from the administration of excessive amounts of water. It was vital that the fluid intake should exactly balance the insensible loss—it should be exactly 1 litre plus the volume of any urine secreted. A mineral free and protein free diet should be given and the necessary high caloric value should be provided by carbohydrates and fats. Diuretics were useless at this stage and could do nothing but harm. The third and fourth stages were the early and late diuretic and corresponded with tubular regeneration. Here there was a return of urine flow with at first very poor tubular function. The urine was an almost unaltered glomerular filtrate. Thus there was a great loss of essential substances, and in particular water and salt. This loss must be made good. Potassium loss was less severe and might be readily overcome by the use of a diet providing plenty of fruit. The diuretic phase lasted, as a rule for the same period as the preceding anuria.

In opening the *Pathological Museum*, Professor SHEPHERD made one of the briefest speeches of the entire meeting. All credit for the arrangement of the museum should be said to go to Dr R. C. Nunn and other members of the pathology department, and he added that it had taken him four hours to go round the museum.

The exhibits were placed in nine groups usually representing the special branches. The paediatric section contained demonstrations of congenital abnormalities of the newborn and of infants and a fine series of colour photographs. The gynaecological and obstetrical section included a series of specimens illustrating radical surgical procedures, and an exhibit of the modern classification of pelvic types. The neurology section presented a series of pots in the classical style set against a mural scheme of electro-encephalograms. A combined bacteriological and paediatric demonstration dealt with the clinical and laboratory aspects of toxoplasmosis in a way that would prevent anyone from regarding the problem as being academic and unimportant. In the section of orthopaedic surgery a demonstration of skeletal abnormalities induced in the developing chick embryo by the injection of insulin aroused considerable interest. The surgical section besides some uncommon surgical conditions and recent operative procedures had a demonstration of hydronephrosis induced in rats. Pathology and bacteriology in a combined exhibition showed several series of teaching specimens amongst which that on bone pathology was perhaps outstanding. Research in progress was also illustrated.

(to be continued)

older patients properly at home. They wanted more help and advice from consultants, which was often not available except in certain areas. They lacked facilities for physiotherapy which would allow rehabilitation after illness, adequate treatment of chronic rheumatic disease, and proper management of patients with a hemiplegia. This last point was heavily underlined by a film which Dr MARJORY WARREN showed, demonstrating the technique she has evolved for dealing with such cases. While simple to carry out in hospital, it would be most time consuming for any general practitioner on his daily round. Another lack felt was the need for a pathological service outside hospitals, so that blood counts and other simple tests could be carried out on domiciliary visits.

There was also considerable agreement among those who have to care for elderly patients in hospital. Dr C. T. ANDREWS, of Truro, produced statistics showing the increasing number of old people needing the hospital services of Cornwall. On one day recently, over 40% of the hospital cases in his area were over sixty years of age. When the district nursing services were investigated, half the visits were paid to patients in this age group. These figures were very similar to those produced by Dr W. E. FITZGERALD, M.O.H. for Southport, under whose auspices a determined effort has been made to produce a coordinated geriatric service for the town. Clubs, clinics, social welfare activities, and hospital beds are being closely linked in a promising attempt to meet the needs of the old folk who are a peculiar problem in such seaside areas. The importance of such a linkage between hospital services, welfare authorities, and the general practitioners was stressed by several speakers, and in particular by Dr E. B. BROOKE, of Carlisle. In his opinion, the centre of gravity in geriatrics was the home of the patient and not the hospital unit. The family doctor must steer the ship, aided and abetted by the physician to the elderly, the district nurse, the home help, and welfare workers. Before admission to hospital of any old person there should be a medical and social assessment of his needs. Otherwise beds would be blocked by cases which could be nursed at home. This practice, which is in operation at Bradford, should also be amplified by the organisation of outpatient clinics. Thus, and thus only, can be avoided the long, meaningless waiting list, which the practitioner dreads. Geriatrics is essentially team work, not merely another speciality in medicine. Unless the family doctor is a member of the team, both in hospital wards as well as in the homes of his patients, those patients will suffer. In country districts, the cottage hospitals could play a larger part in the care of old people than they do. There is need for central geriatric units to create a ring of subsidiary wards and clinics around them in order to serve the old folk effectively, and to help the family doctors more than they do at present.

Diagnosis and Treatment

But it is not enough to ease the burden of harassed relatives by admitting the aged sick to hospital at an earlier stage of their illnesses. It is necessary to provide better methods of diagnosis and treatment for those who present themselves. This was the theme of Dr LOUIS CARP, of the Goldwater Memorial Hospital in New York. In a most inspiring address on surgical treatment of elderly patients, he stressed again and again the difference of mortality between emergency operations and those of election. Quoting statistics from several clinics, he demonstrated how preoperative correction of anemia, nitrogen imbalance, and fluid lack paid dividends. Improved methods of anaesthesia and the right psychological approach to the patient also cut down mortality very appreciably. Apart from his wide technical scope, Dr Carp was of great service to those attending the meetings of this section by telling them of the developments in the United States, especially on the care of those

suffering from mental changes in old age. His that Britain led the world in geriatrics came as a tribute to his hosts.

The clinical and pathological themes were dealt with by Dr VISCHER, of Basle, who referred to the of necropsy on a series of 1826 cases from his, and by Dr HIRSCH, of Brussels, who discussed problems of arterial disease in the aged. Both authorities thought that arteriosclerosis was the cause of a shortened life span and "the scourge of temporary humanity." Degenerative pulmonary in the aged with pulmonary fibrosis was the closest to the heart of Dr ROBERT EVANS, of Liverpool. Prevention and early treatment by antibiotics and antispasmodics could do much to reduce the mortality in this group of complaints. As in other pathological conditions of old people, it was delay and halfhearted therapy which produced infirmity to fill hospitals with chronic cases. These were too frail for their relatives to accept back home with open arms, even after recovery. Unless more hostels were forthcoming to receive these patients, they would create a problem which might conceivably upset both hospital and general practice aspects of the National Health Service. Here early diagnosis, prompt treatment, co-operation of general practitioner and consultant, and co-ordination of nursing and welfare services with the hospital facilities are all essential. This was the unanimous verdict.

PATHOLOGY AND BACTERIOLOGY

President Prof H. L. SHEEHAN

Recent Advances with New Methods of Microscopy

Dr ROBERT BARER, who opened this symposium, said that when using simple lens systems to examine unstained living tissue, very little fine detail could be made out, owing to the transparency of the tissue. This difficulty could in some measure be overcome by using ultraviolet light, but further complications at once arose, for microscopes designed for use with ultraviolet light required special lenses of quartz or fluorite and these had certain inherent disadvantages. Achromatic lenses made to satisfy these conditions could be corrected for only a single wave length, and as a result there was difficulty in focusing the image. A mirror, unlike a lens, was free from chromatic aberration. This illustrated one of the advantages of the reflecting microscope, the magnifying system of which consisted entirely of mirrors so that an object focused with visible light would remain in focus for ultraviolet light. A further advantage was the greatly increased resolving distance, compared with optical microscopes, giving the same final magnification. In a purely reflecting microscope the mirrors must be, not spherical, but of more complex curvature, but spherical mirrors can be used successfully in a system which embodied both reflecting and partly refracting principles. Microscopes of this type had been adapted to provide a means of investigating the ultraviolet absorption patterns of objects such as minute crystals and single cells. This method could provide valuable information about the disposition of the chemical constituents of cells. Further modification of the same instrument, using a different recording system, enabled analysis to be carried out at the infra red end of the spectrum. The absorption patterns produced in this region, while very complicated, were also very characteristic, they were the "fingerprints" of the molecules.

Dr A. F. HUGHES showed a time lapse cine film illustrating the appearance of various cells in tissue culture. Films of this type emphasise dramatically the limitations of knowledge of the living cell.

Mr R. KING, speaking in place of Mr S. SMITH, observed that by ultraviolet light the potential resolving power of the microscope could be approximately doubled.

DISCUSSIONS

the Sympathetic Nervous System in the Genesis of or Hypertension and its Effect upon the Eye

F H ADLER (Philadelphia), the opening speaker, laid out the need to identify the main factor responsible for that peripheral vasoconstriction which is so intimately associated with hypertension. Theoretically, the calibre of the vessels might be narrowed by nervous impulses acting upon their walls, whether directly or by the action of some chemical activator. Such a substance might alternatively produce its effect through the mediation of the medullary centre. It would appear that a humoral substance influencing the actual vessel wall affords the most reasonable explanation. The question then arises why we should ever expect sympathy to alleviate hypertensive damage. According to Professor Adler, relief is attained through a flattening of the "pressure peaks." When the average level of pressure is abnormally high, a relatively slight change in cardiovascular adjustment may precipitate a damage during which the retina may suffer damage, or possibly a fatal outcome may ensue. High average pressure levels may be tolerated unexpectedly well, but small increments are dangerous.

S SCHIFF-WERTHEIMER (Paris) drew attention to the number and variety of the influences jointly responsible for regulating the pressure level. The endocrine system, with all its intricate interaction, is a factor difficult to assess and apt to be neglected. Ophthalmology often enables us to differentiate between the reversible and irreversible phases of hypertension, but final prognosis cannot properly be given on the basis of fundus findings alone.

R HEDLEY ATKINS emphasised that hypertension becomes almost as great a scourge as cancer. He records the retinal changes of malignant hypertension in earnest of essentially similar processes afflicting the kidneys. With regard to the rival operative methods, Dr ATKINS came out in favour of the Smithwick procedure and he emphasised how much the symptoms may be alleviated in wisely chosen cases, not over the age of 55 years. Relief of headache is perhaps the most striking benefit, even among those patients who fail to exhibit any lasting fall in the blood pressure after operation.

R A J BEDELL (U.S.A.) deprecated the use of the modifying adjective "malignant" in describing severe phases of the disease. He prefers to designate them "fulminating" cases. Dr L S TASSMAN (U.S.A.) outlined the importance of emotion, and Dr P LILLIART (Paris) emphasised that fragility and permissibility of the vessel walls were of greater significance than the vascular calibre.

Local and Social Aspects of Heredity in Ophthalmology—This discussion was opened by Prof LAURENCE HEDDER (U.S.A.), Miss IDA MANN (Australia) and Prof FRANCESCETTI (Geneva). Professor FRANCESCETTI described researches pursued with the help of D KLEIN, J ORVI, and J BABEL upon neuro-ophthalmological corneal inherited diseases. Professor SNYDER spoke of the overlapping of heredity with environment in the selection of various ocular defects. Miss MANN described some of her animal experiments and emphasised many cases of inherited disease could be prevented by means of frank individual explanation to married couples contemplating parenthood.

OTHER FUNCTIONS

On Sunday July 16, Professor NORDENSON laid a wreath on the memorial tablet to Sir William Bowman at St James's Church, Piccadilly.

Dr STEWART DUKE ELDER, who was in every sense the founder of our special branch of ophthalmology, just as he was the first president of our Ophthalmological Society.

But renowned as he was throughout the world as a scientist who made immense contributions to our knowledge, respected as a surgeon, a physician, and a teacher unequalled in this country in his time, he is remembered still far beyond the boundaries of this country, for his kindness, his sincerity, and the warmth of his personality.

On July 18 Mr Aneurin BEVAN, Minister of Health, received congress visitors at the Tate Gallery on behalf of the Government. Reception was also given by the Royal College of Surgeons, the British Medical Association, and the Royal Society of Medicine. Sir Cecil Wakeley, F.R.C.S., conferred honorary fellowship of the Royal College of Surgeons on Dr Bailliant and Dr Derrick T. Vail (Chicago). Dr A. J. Ballantyne (Glasgow) received the Nettleship medal from Mr Maurice Whiting, president of the Ophthalmological Society of the United Kingdom.

At the official banquet of the congress, held on July 20, there were nearly a thousand diners, and the chief guests were Mr LEWIS W. DOUGLAS, the American ambassador, and Mrs. Douglas.

In his closing speech to the congress, Professor NORDENSON spoke warmly of its success, and said that the venue of the 1954 congress would be decided later. Brief speeches were also made by representatives from the various continents—Prof L. GUGLIANETTI (Europe), Dr G. STUART RAMSAY (North America), Prof M. E. ALVARO (South America), Dr N. F. AYBERK (Asia), Dr R. C. J. MEYER (Africa), and Dr W. J. ROBERTSON (Australia). Sir STEWART DUKE ELDER thanked all his helpers, and particularly Mr Frank Law, the secretary general. He assured the guests of his delight at their presence and his eager anticipation of seeing them again in 1954 if not before.

Special Articles

ECONOMY IN DRUGS AND DRESSINGS

Sir John Charles, as chief medical officer of the Ministry of Health, has addressed a personal letter to members of the staffs of hospitals, in which he quotes the following observations made by the medical advisory council of the Liverpool Regional Hospital Board.

X-ray Films—In view of the high and increasing costs of films both for inpatients and outpatients, economies should be sought wherever possible and particularly in:

- i. *Serial films*
- ii. *Barium meals*—Medical staff should specify in which cases it is unnecessary to continue after say six hours. (The cost of films for barium meals ordinarily varies from 10s. to 25s. according to the number used.)
- iii. *Tomograms*—Medical staff should suggest which layers are essential and which are probably unnecessary. (Cost of a set of 8 tomograms 12 x 15 in is 21s.)
- iv. *Pyelograms*—(Cost of dye for an intravenous pyelogram is 5s.)

It is also recommended that all requests for films by house officers except in emergencies should be countersigned by a registrar.

Investigations—It would appear that there is considerable scope for economy by restricting investigations to those the results of which seem likely to influence the treatment of and so be of ultimate benefit to the patient.

Drugs—(1) The tendency for expensive drugs to be used empirically, and for several such drugs to be combined on the chance that one or other may be of value should be avoided. (2) There is considerable scope for saving in such drugs as penicillin and other antibiotics. These drugs should be given only where there is a clear indication for their use, and in such cases the dosage should be carefully considered and frequently reviewed, preferably by senior members of the hospital medical staff. All cancellation of treatments should be made on the treatment sheet and notified to the pharmaceutical department immediately. (Cost of penicillin is 4s. 4d. per mega unit. Cost of streptomycin is 4s. per gramme.) (3) The extravagant use of vitamins and stimulants, which are too often given as a routine, should be avoided.

1 It was incorrectly stated last week (p. 147) that hospital doctors were receiving the same letter as general practitioners.

INTERNATIONAL CONGRESS OF OPHTHALMOLOGY

A MESSAGE of encouragement from the King and Queen, patrons of the Congress, was read by the Duke of GLOUCESTER when he opened the 16th International Congress of Ophthalmology in London on July 17. More than 2 thousand members, together with several hundreds of associates from 64 different countries, converged on London for this memorable week of activity. The assembly was addressed by Prof J W NORDENSON (Stockholm) president of the International Council of Ophthalmology, who has now been succeeded

by Sir STEWART DUKE ELDER, chairman of this year. Inaugural addresses were also given by the 15 representatives of different continents: Dr E HARTMANN (Europe), Dr JOHN H DUNNINGTON (America), Prof R ARGANARAZ (South America), JAMSIEDJI DUGGAN (Asia), Dr ABDEL FATI TOGBY (Africa), and Dr J RINGLAND ARTH (Australasia). Dr H ARRUGA (Barcelona) then received the Gonin medal from Professor Nordenson, for his eminent services to ophthalmology.

PRESIDENTIAL SPEECH

SIR STEWART DUKE ELDER said that modern ophthalmic surgery dates from the achievement of Jacob Daviel, oculist to Louis XV, who introduced his operation for cataract in 1747 and communicated his method to the Academy in Paris in 1752. But if modern ophthalmic surgery is approximately 200 years old, 1950 marks the centenary of ophthalmology as an independent specialty, for on Dec 6, 1850, Hermann von Helmholtz first demonstrated his ophthalmoscope to the Physical Society of Berlin. It is true that three years previously, in 1847, Charles Babbage, an English mathematician—one of whose other claims to fame is that he invented the first calculating machine—invented a similar and indeed more efficient instrument. But since Babbage allowed his ophthalmoscope to lie in his desk for seven years, to Helmholtz must go the honour of revealing to the world the mysteries of the inner eye and of making ophthalmology an exact science.

Of course the discovery of the ophthalmoscope did not in itself revolutionise ophthalmology. We must look upon Helmholtz's achievement in its proper setting. For the decade centred upon 1850 was the most productive and the most exciting in the whole history of medicine. Charles Darwin, Claude Bernard, Carl Ludwig, Virchow, Bright, Addison, Pasteur, Lister, Morton, and Simpson in 1847 were contributing their new ideas, and the whole edifice of medieval medicine was going up in flames.

In ophthalmology the new world opened by Helmholtz was explored with enthusiastic zeal, and the first decade saw the work of Bowman and others on the minute anatomy of the eye, of Donders on refraction and the prescribing of spectacles, and of a host of others on new techniques in surgery.

"In the hundred years which have followed, I think it can be said that we have been reaping the fruitful harvest of this prodigal sowing, consolidating and expanding, but adding little that is fundamentally new. The only great revolutionary concept that has been added to the techniques of surgery is the treatment of detachment of the retina by Jules Gonin."

For further advances, new techniques are needed.

"I think it may be that we are starting a completely new chapter and entering upon another revolution. We do not yet have the background or perspective to say whether this resurgence of medical thought is related to a more widespread and general stirring of the human spirit among the nations, but it coincides with a time when the material power in the hands of man has seen the prodigious revolution of atomic energy. From the structural point of view, instead of Virchow's microscope, we are now equipped with the electron microscope, which is opening out a new and more intimate universe within the cell. From the functional point of view we can follow metabolic processes with radioactive elements through all the intricacies of metabolism. The age of biophysics and biochemistry has dawned and instead of merely describing and mourning over the structural ruins which disease has left behind it, the change in outlook today, as I see it is to probe more deeply, to examine the more subtle nature

of the initial defect, to pass from cellular pathology to intracellular chemistry."

Ophthalmology, said the President, is leaving its century of adolescence and is entering its second century of adult life, when it can begin to formulate an integrative philosophy based on a knowledge of the first principles of health and disease.

SCIENTIFIC PROGRAMME

A series of visits to Edinburgh, Glasgow, and various provincial teaching centres in England was arranged. Parties of visiting ophthalmologists during the week immediately preceding the congress. The week of the congress itself demanded unceasing activity on the part of those who wished to avail themselves of the ophthalmological feast. Three concurrent sessions, whose number increased to five on one occasion, were needed in order to permit the delivery of more than 140 communications exclusive of the opening papers for the two main discussions. Numerous physiological and pathological demonstrations were staged at the Institute of Ophthalmology, whose main departments were open to inspection throughout the week. The programme also included over 60 ophthalmological films, operative sessions, and demonstrations in radiotherapy, physiotherapy, color television for surgery, and orthoptic methods. The latest devices for fitting of artificial eyes and of contact glasses were also displayed.

Elaborate preparations had been made to assemble material for a series of museums, so that it was possible to see, separated by distances of only a few yards, a wealth of clinicopathological items, including first-aid, histological specimens, coloured fundus photographs, case records, and investigatory devices. One exhibition was devoted to the principles of illumination, another to historical books, and another to the evolution of spectacles and surgical instruments, together with various objects of historical interest. The exhibition devoted to social and industrial ophthalmology contained a mass of carefully sifted information about miner's visual problems and a wide range of protective devices for workers in dangerous occupations.

The work of St Dunstan's and of other organisations concerned with the welfare and rehabilitation of blind people was carefully set forth. Gone are the days when loss of sight limited the victim to a few menial tasks. Granted the necessary training and encouragement, blind people can make their choice from an enormous range of skilled occupations. Indeed there are numerous important jobs for which they have a greater aptitude than the average possessor of normal sight.

Ample space for all these exhibitions was available at the London School of Hygiene and Tropical Medicine and the Wellcome Medical Foundation. At St Paul's Town Hall there was an attractively organised display of books, drugs and surgical and ophthalmological instruments.

In England Now

uring Commentary by Peripatetic Correspondents

Borcott used to say that of all men histologists are most idle. They sit on tall stools they puff pipes and they twiddle the handles of their microscopes. Do they meditate on the function of the neuroglia, innerness of Bielchowsky's stain or on their of a legacy from Aunt Agatha? Or do perhaps mes of xviii induce dreams of hours in robes with rose bengale and alizarine? Our visits of the viscous are few and far between and these are ones whose answers we never hoped to learn. We therefore in extraordinary debt to the American who has printed a translation of an apologia from the of the late Pio del Rio Hortega, down of those followed Ramon y Cajal. What de Quincey did to victims of the poppy this Spanish savant to the devotees of the stain pots the foetid imbedden, and the sacrificial razor. He made no bones of it, the histologist is a creative artist. That his may have "useful results" that he may establish thing which will pro tem pass as a working basis for 'truth' does not influence his claim. cannot be a virtuoso of histology without being former. Every still unsolved problem of biology isically a technical one, and he who delegates work to the technician seldom devises a new nique. He who devises no new technique rarely nces the science which he professes. And the reward e true histologist lies in the creation of no s mulacrum of an entrancing reality unseen by any previous eye. That person has not the makings of a histologist, after being stared emotionallly before a perfect oscopic picture does not look for someone of a lar sensibility with whom to share it like a child fully showing his new toy. Thus did Hortega lift rmer of the curtain and we wonder at our past dness. Histology is a cult which binds a secret herhood. Looking at our colleagues we recognise indoctrinati and the neophytes. Is that pink stain he left forefinger an initiation mark? They have ples, redolent of paraffin wax and strong tobacco e's which the curious may learn in 'Bolles Lee a language entirely of their own. Montague James told some stories which should warn us against ustave prying into the mysteries. young men should ak twice or more before they take the plunge. The estigator's spirit burns, without being consumed in amp of three flames: the many-coloured flame of stic sensibility, the bright white flame of eagerness discover new truths, and the blue flame whose tex soars upwards and seeks eternity. We would use those who have any doubts to stick to a rocker rotome and "H and E."

It was late afternoon and the last few donors were igned on couches by the windows which overlook old Roman bath. The concert-room rose high above, eighteenth-century magnificence, outside, the ram- n faces of the Roman Emperors gazed in stony martial enty across the bath in which the goldfish swam r below, for it was a warm spring day at the end March, which, very correctly, was going out like a b

length, all was done. The swing doors had swung ind the last folded stretcher as it was carried out to jacked in the lumbering three-ton lorry which had ted outside through the hot afternoon. The doors med and the great vehicle roared as it moved slowly y from the doors of the Bath Room P-mp. (Your ion, madam, the Pump Room B-th.) The lady r, with the male orderly seated beside her, elected convenience to drive out under an old arch on to the n street, and not to turn back by the way she had red earlier in the day. As Leviathan approached the i it became apparent that clearance at the roof if e were any, would be slight. Lorry and arch drew rer, and lorry edged underneath. The male orderly

gazed aloft with soft anxious eyes. All was well: the balmv air of B-th filled a clear nine inches between the respective roofs. Yet *subito* a sudden jarring crash stopped the triumphal advance. The orderly looked up expectantly awaiting the fall of masonry, but to his surprise the arch was further away than before. But alas the gam above had sadly been offset by a subsidence below and looking behind he saw the wheels up to their axles in Roman pavement.

On either side of the area were shops with cellars below. In one of the cellars an old man stonied merchandise was surprised at the sudden fall of light followed by a pair of lorry wheels. A crowd of B-thers (B-thomians? B-thians?) gathered and also a superintendent of police, the city engineer, a breakdown team, another breakdown team and then reporters and a photographer from the local press. Here the orderly (to whom Kipling would have warmed because he was a man of considerable resource and sagacity and for all I know, best beloved suspense) showed himself equal to the occasion. He held a quick press conference at which he stressed the need for blood and made a moving appeal for more donors. Meanwhile the first breakdown team had done considerable damage and there was danger of the shops on either side collapsing. Breakdown team no 2 had a go.

A dance had been arranged in the Pump Room that night and people began to arrive for it. The dance committee canvassed the crowd of many hundreds that surrounded the lorry and so successfully that all the tickets were sold and the B-th Cycling Club looked like having the most successful and remunerative dance of its long existence. As a mark of gratitude all the members of the blood transfusion service were invited in and given a free supper.

Late that night the second breakdown team got our poor lorry out and it drove off leaving behind it a couple of hundred pounds worth of damage, and a B-th which sorely needed a plug.

And so to bed.

The derisioning of petrol seems not to have increased the accident-rate in our parts, but what has struck me very forcibly of late is the danger of attending school. No fewer than six little boys in today's fracture clinic had been injured while pursuing their lawful occupation—pushed off walls, trodden on by bigger boys or (shameful to say) hit by a stone thrown by a girl. P.T. too claimed some victims. True there were a few odd grown-ups who had dropped billets on their toes in the steelworks or caught their leg between tubs down the pit, but 6 schoolboys out of the 20 new patients shows that school is definitely a hazardous occupation. And there is no question with them of compensation or sickness benefit—not even of wanting a doctor's note. Just a curt remark from the orthopaedic registrar that an arm in plaster does not prevent one from using one's head, and back they go to their life of trial and tribulation.

Lines inspired by Dr G Catherine Evans's speech at Southport

The Cons and the Specs
Draw whacking great cheques,
Mr Chairman. Let's not pity those
It's the poor old G.P.s
Who get the hard cheese
And the hardworking Shmos and Jhos
Those emergency jobs
Aren't all done by the nob's.
Where are they at weekends? God knows.
And who fills the gaps?
Why the G.P.s, poor saps
And the downtrodden Shmos and Jhos
Some think Mr Newell
A regular jewel
I can't say that I'm one of those
It's the lonely G.P.
Who is my cup of tea,
And the put-upon Shmos and Jhos.

Referring to the use of proprietary preparations, Sir John Charles suggests that, save in exceptional cases, doctors should seriously consider, before ordering a proprietary preparation, whether the alternative standard drug could not be ordered without detriment to the patient's condition. "At consultative clinics it is desirable that drugs prescribed should be according to the *National Formulary* where comparable, since prescriptions issuing thence must often become almost obligatory on the general practitioner when the patient returns to his care."

"None of us," he adds, "will wish to cause the Health Service to cost more than is necessary. I shall greatly value your help in effecting in this field the substantial economies we believe to be possible."

Parliament

The-Medical Bill

IN committee in the House of Commons on July 18, debate continued on Dr CHARLES HILL's amendment to secure that any complaint referred to the penal cases-committee of the General Medical Council must be supported by a statutory declaration. A practice had lately grown up, Dr Hill said, under which the Ministry of Health sent certain papers to the G.M.C. but did not put in any statement of complaint. For example, a case had recently been heard by the National Health Service tribunal and the practitioner found not guilty, after which the Ministry of Health sent the papers to the G.M.C. in case they were interested. The point of his amendment was that a Government department should not be freed from the obligation of appearing and making a complaint, and being questioned about it, any more than anyone else.

Mr ANEURIN BEVAN said he was now prepared to give an assurance that, where a doctor had been acquitted by the tribunal set up under the National Health Service Act, the Ministry would not send the papers to the council. However, he must make it clear that the decisions of the tribunal were published, and that the G.M.C. might take cognisance of them and might start proceedings themselves. If in such a case they asked for the papers, these would have to be supplied.

In view of the Minister's assurance the amendment was withdrawn.

Lieut Colonel WALTER ELLIOT moved an amendment with the object of discussing with the Minister a point arising out of the Spackman case. Under the Bill, a finding in a High Court or Court of Session of the United Kingdom or the Republic of Ireland that a practitioner had been guilty of adultery with a certain person was to be taken as conclusive. Colonel Elliot agreed that much could be said for the argument that the G.M.C. should not retry a case, but nevertheless new facts might become evident in a hearing before the council. Secondly, why should this ruling apply only to cases where a doctor had been found guilty of adultery? Surely there were other offences of which he might be judged guilty involving the stigma of infamous conduct in a professional respect, such as slander or a bastardy order. In the past it had been held that an investigation held in the courts for one purpose should not be taken as more than prima-facie evidence that there was a case for inquiry before another court.

Mr BEVAN thought it was generally agreed that it would be quite wrong for the G.M.C. to retry a case which had already been tried by a court of high standing. Therefore it could be taken for granted that in the case of adultery the decisions of the court would be accepted by the G.M.C. But in other cases—o.g., the case of an affiliation order—the G.M.C. might feel that it was open to them to reconsider the decision.

After a lengthy debate Mr Bevan eventually agreed to look at the matter again. But he said it must not be inferred that the language of the sub-section could be altered.

Mr RICHARD FORT moved that the period which a doctor could lodge his appeal to the Council should be increased from 28 days to 3 months. Mr BEVAN said he could not accept an amendment which would allow a medical man to continue to work for 3 months after the gravest doubts had been cast on his professional capacity. The medical societies and the B.M.A. had suggested 21 days. The amendment was negatived without a division.

VISITORS OF MEDICAL SCHOOLS

Mr I. J. PITMAN moved an amendment from inspection any place of instruction which was the direction of any body which at any time during the preceding six years had received a grant from funds through the University Grants Committee. The procedure proposed in the Bill was, he said, principle, and unwise, because it divided responsibility between the universities and the G.M.C. The inspectors to medical schools would be inspectors of the staff, the curriculum, and hours of teaching, and even part of the methods of instruction. Did the G.M.C. really take this responsibility? The best method was a visiting committee which was invited into the unit by the teaching university.

Mr BEVAN said he was surprised to see this amendment for the provisions in the Bill followed the recommendations of the Goodenough Committee. So far as he knew, they had received the unanimous support of the university authorities, at least no objection to them had been raised. If the G.M.C. inspections were vexatious to university authorities, they could make representations to the Privy Council to alter the directions. He was certainly inquiring whether the universities were about this matter, but he could not promise that substantial alterations could be made to the clause.

The committee stage was concluded.

QUESTION TIME

Analgesia in Childbirth

Mr PETER THORNEYCROFT asked the Secretary of State for Scotland how many domiciliary confinements in the Glasgow area during 1949 were attended by midwives and in how many of such cases gas and air analgesia was administered for the purpose of relieving pain. Mr H. McNEIL replied: In Glasgow 4680 domiciliary confinements were attended by midwives alone during 1949, and in 17 of these was gas and air analgesia administered.

Mr THORNEYCROFT asked how many gas-and-air machines were available in Glasgow on Dec 31, 1949, and how many of such machines were on order at that date. Mr McNEIL replied: None for domiciliary midwives was available on order at Dec 31, 1949, since then 6 machines have been available and 24 more are on order.

Mr THORNEYCROFT asked why, during the year 1949, a woman confined in her own home and attended only by a midwife received gas and air analgesia in Berwick, Lothian, Inverclyde, Kirkcudbright, Midlothian, Peebles, Roxburgh, West Lothian, Zetland, Coatbridge, Dunfermline, Falkirk, Glasgow, Hamilton, Caledonia, and Rutherglen, and what action he proposed to remedy this situation. Mr McNEIL replied: There is in each area a view that the necessary arrangements for the training of the midwives were not far enough advanced, or that gas and air machines were not far enough available. I asked the local health authorities in all these areas to review the position as quickly as possible.

Tuberculosis Patients in Swiss Sanatoria

Mr D. T. LLEWELLYN asked the Minister of Health whether he was aware that there were at present 1000 beds in Swiss sanatoria that there are 8000 notified cases of tuberculosis in Great Britain waiting for proper treatment and therefore spreading infection, that the cost of treatment in sanatoria need not exceed a basic 30s a day, and that he would now make sufficient currency available in connection with the Chancellor of the Exchequer, with a view to enabling tuberculous patients to fill empty beds in sanatoria. Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, replied: There is no power to provide or pay for treatment under the National Health Service Act outside this country.

gazed aloft with soft anxious eyes. All was well, the balmy air of B-th filled a clear nine inches between the respective roofs. Yet *subito!* a sudden jarring crash stopped the triumphal advance. The orderly looked up expectantly, awaiting the fall of masonry, but to his surprise the arch was further away than before. But alas, the gain above had sadly been offset by a subsidence below, and, looking behind, he saw the wheels up to their axles in Roman pavement.

On either side of the arch were shops, with cellars below. In one of the cellars an old man storing merchandise was surprised at the sudden fall of light, followed by a pair of lorry wheels. A crowd of B-thers (B-thomians? B-thmeans?) gathered, and also a superintendent of police, the city engineer, a breakdown team, another breakdown team, and then reporters and a photographer from the local press. Here the orderly (to whom Kipling would have warmed because he was a man of considerable resource and sagacity and for all I know, best beloved, suspenders) showed himself equal to the occasion. He held a quick press conference at which he stressed the need for blood, and made a moving appeal for more donors. Meanwhile, the first breakdown team had done considerable damage, and there was danger of the shops on either side collapsing. Breakdown team no 2 had a go.

A dance had been arranged in the Pump Room that night, and people began to arrive for it. The dance committee canvassed the crowd of many hundreds that surrounded the lorry, and so successfully that all the tickets were sold and the B-th Cycling Club looked like having the most successful and remunerative dance of its long existence. As a mark of gratitude all the members of the blood transfusion service were invited in and given a free supper.

Late that night the second breakdown team got our poor lorry out, and it drove off, leaving behind it a couple of hundred pounds worth of damage, and a B-th which sorely needed a plug.

And so to bed

* * *

The derationing of petrol seems not to have increased the accident rate in our parts, but what has struck me very forcibly of late is the danger of attending school. No fewer than six little boys in today's fracture clinic had been injured while pursuing their lawful occupation—pushed off walls, trodden on by bigger boys, or (shameful to say) hit by a stone thrown by a girl. P.T., too, claimed some victims. True, there were a few odd grown ups who had dropped billets on their toes in the steelworks or caught their leg between tubs down the pit, but 6 schoolboys out of the 20 new patients shows that school is definitely a hazardous occupation. And there is no question with them of compensation or sickness benefit—not even of wanting a doctor's note. Just a curt remark from the orthopaedic registrar that an arm in plaster does not prevent one from using one's head, and back they go to their life of trial and tribulation.

Lines inspired by Dr G Catherine Evans's speech at Southampton

The Cons and the Specs
Draw whacking great cheques,
Mr Chairman. Let's not pity those
It's the poor old G P's
Who get the hard cheese,
And the hardworking Shmos and J'hos.
Those emergency jobs
Aren't all done by the nob's
Where are they at weekends? God knows
And who fills the gaps?
Why, the G P's, poor saps,
And the downtrodden Shmos and J'hos
Some think Mr Newell
A regular jewel
I can't say that I'm one of those
It's the lonely G P
Who is my cup of tea,
And the put-upon Shmos and J'hos

Letters to the Editor

SIGNIFICANCE OF THE DISCOVERY OF THE EFFECTS OF CORTISONE

SIR,—Professor Pickering's analysis fails to do justice to psychosomatic medicine, because he separates genetic and environmental influences as if they had no bearing on each other. An environmental stress can easily be shown to produce different effects on individuals of different physique and as easily be shown to produce different emotional response in people of different character and temperament. Over simplification of causation has been one of the great temptations and curses of medicine. Selye's thesis has been briefly and rather refreshingly criticised by Meiklejohn¹, but there is, of course, no reason why an adrenal adaptation mechanism should not play a major part in psychosomatic disease, and many reasons to make this a good working hypothesis.

Nobody could deny that "alarm," however induced, has an emotional effect. The question raised is whether the emotion experienced is the result of physiological disturbance caused by the injury or alarm stimulus, or whether the emotion itself provokes disturbance. This is the old and insoluble problem of the hen and the egg, but it is certain that the capacity to experience emotion must exist for certain stimuli to be appreciated at all.

We can accept "character formation" by external influences as an explanation of personality, but not as the whole explanation. Inherited constitution is the matrix on which education operates, and we cannot simply shut our eyes to the evidence for inherited features in character because we cannot influence them but can influence the environment. Professor Pickering says that because "a single mental state" (e.g., anxiety) is associated with a variety of disease entities, the psychosomatic conception is invalidated. I suggest that this completely ignores everyday experience. Of a party of children submitted to an exciting experience, the majority are perhaps pleasurably elated, but one vomits, another has diarrhoea, another asthma, another perhaps migraine, and another wets the bed; another may even have an epileptic fit. I suppose these symptoms to be often, or even usually, constitutional body-patterns of response to emotional experience, the psychosomatic conception involves a deduction, as a working hypothesis, that such responses may produce structural changes and that these are not always reversible. The mechanism of bodily response in particular syndromes has been little studied and presents numerous lines of research.

Professor Pickering gives as a second reason for rejecting the psychosomatic conception that "psychotherapy seldom produces dramatic or repeatable effects in these diseases" (This is rather odd phraseology, a disease is either cured or it is not, and if you need to repeat the treatment it is not cured.) But there was no need to doubt the association of tubercle bacilli and phthisis before we had streptomycin, nor is streptomycin the cure we hope for. Psychopathology is a young science compared to morbid anatomy, and the two terms are comparable. Psychotherapy, like other therapies has been the economic basis for research in psychopathology, it has had its occasional cures down the centuries, and with better understanding and technique, its useful range has increased, like that of surgery. It has its quacks and its orthodox blunderers like any other branch of medicine. Freud, least of all, expected it to become a panacea. The effect of his work on medicine can be compared to Harvey's or Pasteur's—work which led us to understand some part of the mechanism of

vascular disorders and infections. We do so, their work because we have waited a long time for medical problems. We look, in fact, for slow progress in the understanding of psychosomatic disease, "dramatic effects" from psychotherapy, and conspicuous and slowly accumulated undertaking prevention.

In medical practice we must, perforce, make limited conceptions, as of organ disease and causes, but I find it depressing that professional medicine should become, in the justifiable technical understanding and equipment, divorced from a philosophy of medicine. I rejoice with Professor Pickering that the fashion of "explaining" all our diseases as due to focal sepsis has waned, but is not to deny that local suppuration can cause widespread bodily disturbance. We might well say of causative medicine what Croce has said of philosophy—they are mostly right when we affirm, mostly wrong when we deny. But perhaps we do best merely to keep an open mind.

Bickley, Kent

DUNCAN LEITCH

SIR,—In his interesting lecture published in your issue of July 15, Professor Pickering refers to several causes of disease and mentions three "etiological influences" which have been claimed as responsible, not only for the rheumatic diseases, but for a much wider field of physical disorder. He might also have mentioned an attempt to incriminate "malnutrition," vitamin and mineral deficiencies, and other defects of feeding, as causes of so large an area of disease as to include, for example, dental caries and delay in labour.

It is inevitable that these attempts to unify apparently various factors of etiology should occur to the thought of workers in medical research and practice because they are expressions of a deep desire of man to resolve chaos and disarray into organic order. The tendency to such unity or unification can be traced through all the works of the artists, indeed with unity there is little art, whether the medium be music, painting, or the written word. Whereas it is of absorbing interest to ponder upon the function of the idea, the reality of unity in human satisfaction, this is not the purpose of my letter.

It is true that "focal sepsis" is quite discredited as a cause of any group of diseases, or even of any definite disorder such as arthritis. As time passed during the early phases of enthusiasm for dental extraction, other efforts to remove centres of infection, accumulated experience, often unwillingly accepted, showed that there was no causal association between the septic focus and the painful creaking knees. In short, the general experience of the practice of the theory of focal sepsis, the less was the evidence of its truth. It is, however, that what is called "psychosomatic etiology" is totally different from focal sepsis in its relation to disease, because, if for no other reason, clinical experience gives increasing confirmation of its truth. Professor Pickering dismisses the psychosomatic hypothesis as of the same value as that of focal sepsis and lists objections which would appeal to the "simple minded student as valid for rejection of the theory. He might indeed be simple minded if he found in these objections any cogent argument against a very close association of physical disorder and states of mind and feeling.

Now, most modern specialist physicians are biochemists and manipulators of various engines of diagnosis, it is not easy for them to realise, until the end arises from their own personal selves, that the human personality is one indivisible unity of mind with emotions and the physical body. The two are inseparably married, they are one. This apparently dogmatic

nt will be questioned by many, but I believe own and other clinical experience of the whole—not just the level of his blood chemical sub—that there are two entities combined in our personality, and that therefore a stress affecting I provoke an adaptation reaction in both moieties only is the development of firstly "functional ance" and later the secondary organic lesion h very many cases of peptic ulcer and of pelvic ions in women) associated with mental and al states beyond the grasp of chance, but also, ommonly observed, certain visceral reactions, such rt bert (and even contractions of the non pregnant) are an immediate result of sudden strong nal stimuli. The mind can scarcely think or the t" feel but there is some answering physical ise. It is already recognised by almost all, if not micians that some diseases are so closely related ntal states that the "psychic" aetiology is not oned. Thyrotoxicosis gastric spasm of peptic a very large amount of all varieties of menstrual bance in the young, and inertia of the uterus in r are all examples of conditions which would pear from civilisation could it be relieved of ever asing tension, anxiety, and fear. present we are studying the results of the established ise, mostly without a thought for the whole per ily, "temperament," and domestic and social ound. But when the physiologists begin to teach elation of emotional states to physical reaction, and far this will lead to disturbance of function and ic changes, we shall have a more solid foundation the study of the aetiology and treatment of an widening range of disease.

creasing experience of the theories of focal sepsis certain nutritional defects as causes of disease found n wanting, but most of us who see sick people, n to them talk, and examine and treat them, are vined that "psychosomatic" aetiology is indeed a ent factor. If fear could be weighed and measured, re would be little reluctance to place it and other otions in their proper place in aetiology, but, as ony said, "There's beggary in love that can be oned." I ask myself "can the completely happy r be ill?" or "can the permanently miserable ever well?" These are theoretical questions which might answered in heaven and hell, but not here. Never- less we have come to associate the buoyant, exalted id with exuberant health, and the anxious, tense, ring temperament with constant ailing complaint.

ALECK BOURNE

ACCURACY IN RED-CELL COUNTS

ir,—Your leading article of July 15, may, I fear, lead the clinician of small experience into regarding red cell count as virtually valueless. But as he as in experience he will realise that one function of clinician is to select those data that are useful for purpose of diagnosis and treatment. When he has nt to do this he will, I think, find the red cell count ntains the value that the experienced clinician persists taching to it.

he statisticians have done a service to medicine ut their choice of terms is sometimes unfortunate. Instance they refer to "minimum" error and probable limit of error." In a red cell count of 5,000,000, minimum error may be nearly half a million, and the ble limit of error nearly a million. The clinician, small experience may infer that the red cell count has recently received from the laboratory must be east half a million out, and probably a million. o confound him I append the blood counts of a ent with pernicious anaemia taken over a year

During that period her clinical condition showed a slow but steady improvement, which is reflected in the blood counts

Date	Red cells (thousands per c mm)	Hb %	C I
April 14 1949	4000	85	1 06
Oct 5 1949	4300	96	1 12
Oct 31 1949	4600	100	1 08
Jan 16 1950	4650	102	1 1
Feb 18, 1950	4400	98	1 11
May 27 1950	5200	100	0 95

If during this period 20 counts, instead of only 6, had been made, then it is likely that a count with an error of $\pm 16\%$ might have appeared—e.g., a count on Oct 30, 1949, might have given 5,360,000 (or 3,840,000) red cells—assuming Berkson's probable limit of error of $\pm 16\%$. If such a count had appeared the physician's clinical sense would have questioned its validity.

I seem to recall a radio story by A. J. Alan, in which he accompanies a mathematical friend on a safe breaking expedition. The safe had a combination lock, and the mathematical (and somewhat criminal) friend knew that the possible combinations were extremely numerous, but, by saying every few minutes "I propose to ignore those results," he quickly found the right answer, and the safe was opened. That in effect is what the clinician does—he ignores certain results. The method, of course, demands care in its application. It can usually be applied safely to a series of counts. But if in doubt the clinician can usually repeat a questionable count—e.g., a count of 5,360,000 on Oct 30, 1949, would be followed on Oct 31 by one of 4,600,000.

The single isolated count is more likely to mislead—the count that appears in response to the request for "a complete blood count please" from a clinician who has not the haziest idea what his patient is suffering from, but hopes that the pathologist (or the radiologist) will make the diagnosis for him. If your article does anything to restrict that type of demand I am sure all clinical pathologists will be grateful.

G. CAMPBELL

ACTION ON TUBERCULOSIS

SIR,—Dr. Ball and his colleagues, in their article of July 22, urging that cases of open tuberculosis should be admitted into the wards of general hospitals state "Tuberculous wards in general hospitals can but lead to a revival of interest in this common disease. Tuberculosis must be brought back into the main stream of medicine." I feel sure that this will be the unfortunate result. They state "Tuberculosis wards in a general hospital are an essential part of sound tuberculosis administration, and lead to efficiency both in preventive and in curative medicine."

Have we any proof of the latter statement? Some forty years ago I took part in an active anti tuberculosis campaign under the leadership of that pioneer in public health, the late Sir John Robertson. We gave the contrary advice, and emphasised the need for improvement in the standard of living, better housing, and provision of sanatoria for segregation associated with complete physical rest and mental tranquillity. It would appear from the steady and progressive decline in the number of deaths in England and Wales from pulmonary tuberculosis (40,766 in 1916, 30,108 in 1926, and 18,798 in 1948) that these measures have been rewarded with very considerable success. The fact that the graph shows that this encouraging decrease throughout the 20th century was only checked during the two great war periods of 1914–19 and 1939–42 lends support to this. In these periods the standard of living and housing degenerated and people were forced to live and work under conditions which we know favour the develop

ment and spread of tuberculosis—i.e., in dark, damp, ill ventilated, and overcrowded rooms, subjected to protracted fatigue with insufficient nutritious food, warm clothing, and medical care of the chills and colds which these conditions created.

The number of deaths from pulmonary tuberculosis in the slums of Birmingham and other large centres at the time of our campaign was three or four times the number in the better housing areas. Dr Ball and others state that "it is a grave reflection on national administration that, throughout Britain, thousands of phthisical patients are left for months in unsuitable homes" yet later in the same column they state "The empty beds are maintained by the discharge of patients as soon as they have reached a stage when adequate care and attention can be given in their own home." We have not the beds or nurses or other staff to treat all the cases of tuberculosis, we have 6000 empty beds in sanatoria because we have not the nurses.

It is proved that the girls who nurse tuberculosis are subjected to considerable infection, even in sanatoria designed for the treatment and cure of pulmonary tuberculosis, and while we admire the training which permits Dr Ball and others to give an indication of reduced infections, we must think of the possibility of infection which may cause a reduction in the nurses in general hospitals. We know that living in hospitals does appear to increase susceptibility to respiratory infections, including tubercle.

The amount of infection from known and unknown tubercle is great. In animals, though it has been possible for many years to apply detection and eradication more completely than we can in man, we have not stamped out tubercle. We have not the means to provide more and more radiography, more and more sanatoria, more and more beds in general hospitals (the Scottish report¹ states that the larger teaching hospitals should be excluded), more and more chest surgeons which our enthusiasts tell us are desperately needed. The excuse for more radiography is that the undiagnosed case of tuberculosis in the general ward is one of the chief sources of infection, yet Dr Ball and his colleagues state "With all patients, particular stress is laid on the need to stop coughing," and "delay in diagnosis is still a major problem and one that mass radiography cannot solve."

The propaganda of fear which speaks of the need for desperate measures fails to convince us of success when these demands are met, for those who have been lucky, or unlucky, enough to be considered sufficiently interesting to be successfully, or unsuccessfully, treated must return to the conditions which rendered them susceptible, probably now worsened by the long absence and the confirmed stigma. As the Brookins Research Institute report stated "Standard of living has a greater effect on health than quantity of medical care." While success with the measures so desperately advocated is unlikely, we know it would follow progressive improvement in the standard of living and housing, the teaching of simple hygiene in schools, and better facilities for the family doctor to treat his patients at home.

Birmingham

JAMES F. BRAILSFORD

SIR,—Much is being said at the moment about tuberculous patients who cannot get into a sanatorium, and the shortage of nurses is always mentioned as a major cause of their plight. At the two sanatoria at which I have been matron since 1939, it has been possible to staff all beds, and I know of other sanatoria where beds have not been closed for lack of nurses. I think too much is being made of the nurse shortage problem,

especially in places where it does not actually exist and so attention is being diverted from the additional wards. Many plans for new wards have been drawn on paper, but so often building and financial considerations have prevented them being put into effect.

With 400 people dying every week from tuberculosis and hundreds more becoming infected, it seems that the position should be treated as an emergency. If it were treated with the same energy and urgency as was the need for providing beds for expected casualties at the start of war, even the crudest for shortening waiting lists would be given consideration.

If a "tuberculosis emergency state" could be declared, I would like to put forward these two schemes:

1. The erection of summer wards. Since we have the money and the time needed for the construction of buildings, let us have quickly-erected prefabricated wards with fronts wide open to the weather, for use from October to May. It would be cruel to put patients into such quarters in the winter, but they would help to shorten the waiting lists during summer.

2. In the sanatoria where beds have been closed for lack of nurses, some of the women's wards might be opened for selected early cases which, apart from supervision by a Sister, would receive no nursing attention.

The physician in charge would need to select patients who could go to the toilet and bathroom and make their own beds (beds provided with spring mattresses do not have to be turned). Despite having to do a lot of work to help themselves these patients would get 22 or 23 hours of rest out of the 24. At present many a home nurse waiting for a bed in a sanatorium, simply cannot get the lack of full time help in the home) take the rest which might save her life—especially if she has children.

MARIE A. SIMPSON
Sanatorium Matron.

LARYNGEAL VERTIGO

SIR,—In your interesting leading article of July 15, you do not mention the prolonged expiratory phase of crying which in some children may end in laryngeal spasm, and is then called a "breath holding attack."

This designation is unfortunate because it is wrongly that the attack is purposely induced by the child, who is accordingly rewarded with harsh treatment. It is true that the sharp stimulus of a cold or a douche of cold water will end the spasm, but reason for giving it must be clearly explained to the parents so that psychological difficulties may be avoided.

London S E 26

JOHN BURNETT

TORSION OF THE GREAT OMENTUM

SIR,—May I reply to Mr Michael Smith's letter of July 15, and his remarks regarding my article of March 15. In the first place, I did not neglect the British literature. I only included in my bibliography those authorities whose evidence supporting my conclusion that my case should be regarded as one of primary torsion of the omentum. Originally, I had concluded my bibliography by saying "I am also indebted to many other authorities too numerous to be cited," but this remark was ruled out of order by the Editor. In his letter, Mr Smith seems to deny that torsion of the whole omentum is an entity yet in his article, to which he refers, he states that "the whole omentum may undergo torsion." I consider that when the torsion extends to the inferior border of the transverse colon, or the greater curvature of the stomach, it is justifiable to consider it a torsion of the whole omentum. Primary torsion of the whole omentum is so rare as to warrant publication of presenting symptoms and signs are neither constant nor well known. These cases are almost invariably diagnosed as an acute abdomen, and, first things being first,

¹ Tuberculosis Service in Scotland *Brit med J* July 8 1950 p 61

acute appendicitis. However, so long as the n is recognised at operation and properly treated, even in the case of the mass, a surgical cure will be achieved.

R. REITHAR

STIMULATION OF PROTHROMBIN-TIME

I was most interested in Dr Lehmann's letter 17 (p 1133), in which he ascribed the irregular obtained in the estimation of prothrombin times to the use of soapless detergents for cleaning the glass. This has also been noted by several investigators, including myself, working in different laboratories in the United States and employing a variety of thromboplastin preparations—e.g., 'Maltine Chlucott,' 'Disco,' 'Apple's placental thromboplastin'. In our laboratory we have excluded soapless detergents for cleaning glassware which is to be used in coagulation studies. Therefore welcome the attention which Lehmann has drawn to this important source of error. His findings are a further study in regard to their theoretical applications.

New York Medical College

A. L. COPLEY

THE ALEXANDER LIBEL ACTION

I read Dr Barlow's article, in your issue of July 15, with the greatest interest. I should like to draw readers' attention to two passages in his account of the libel action.

Professor Samson Wright dealt carefully with this point, and established that what Alexander was referring to as 'primary control' has nothing whatever to do with Magnus's concept of the *Zentralapparat* which refers to centres in the brain stem.

Summing up on this point, the Appeal Judges said:

"The expert witnesses called for the defence say that under s knowledge of these subjects is very limited and of them suggest that he never read any description of Magnus's experiments but was given a second hand account of them which he did not understand."

We had an intimate association with Mr Alexander for some twenty two years and have been with him when he was reading the account of Magnus's experiments as described in *THE LANCET* over twenty years ago. Further, I was at least one person who provided him with a translation from the original in which Magnus wrote his book *Körperstellung*, and I have him what I considered to be the meaning of the passages on p 619. I understood these passages as being the anatomical foundations of a central directing apparatus, its manner of operation, and the manner of operation in the operation of the cerebro-sensory motor, and muscular mechanisms of the body as a whole within the range of animals on which he had experimented.

In claiming no expert standing as a German scholar, Mr Alexander has been responsible for laying Mr Alexander to a charge that he relied upon a person who was not competent to guide him. May I suggest that a reliable translation of these passages should now be made in that their meaning in English may cease to be a matter of dispute?

The reasons for this suggestion are that F. Matthiessen, the late Rudolph Magnus, and the late Coghull, all working quite independently, all working experimentally, and, by the nature of their training and education, working largely without preconceptions about the subject with which they worked, have all reached the conclusion that they could demonstrate the variously called a 'primary,' 'central,' or 'focal and indigenous' integrating guidance and

direction of the living "psycho-physical" or "psycho-organismal" whole. In his work with living persons, Alexander has transcended the work of Magnus and Coghull by providing a technique whereby a person may make use of primary control and may thus guide and control the manner of the performance of his reactions in the best possible way.

Alexander may appear to stand quite alone in making his experiments and in drawing his conclusions from these experiments, but it is possible, as I contend, that he would not be quite alone were the words written by Magnus about *Zentralapparat* translated without prejudice.

Bolton

MUNGO DOUGLAS

SUPPLY OF HEARING-AIDS

SIR,—The recent statement in the House of Commons¹ that the delay in issuing of the 'Medresco' aids is largely due to inability of technicians to fit them fast enough certainly gives a very erroneous impression of what is the actual fact in certain hearing aid distribution centres. One to which I am attached had the supply of aids suddenly reduced, a month ago, to almost exactly half the number per month, which meant a heartbreaking rearrangement of appointments for issue. The only benefit noticed has been the increase in time available to the technicians to attend to the enormous number of minor repairs necessary for the mass produced instruments.

One accessory for which there is a great delay was not mentioned—the individual plastic moulds for the inserted earpieces are not being produced nearly as quickly as the demand requires.

IAN G. ROBIN

INTRAVENOUS PROCAINE AND ANTI-HISTAMINE DRUGS IN BRONCHIAL ASTHMA

SIR,—In 1941 Dos Ghah, Bourdin, and Guio² reported that procaine administered intravenously had proved effective and safe in the treatment of bronchial asthma. I report here on the treatment of 12 cases of severe asthma and 21 of severe asthmatic bronchitis with intravenous procaine and an anti-histamine drug.

Of the 12 cases of asthma, 7 had status asthmaticus, 2 having been in bed for over a month. The 12 patients included a child aged 7 years, and 4 aged about 15 years. The remainder comprised 4 women and 3 men in their twenties, each with a history of recurrent attacks of asthma since childhood. Most of these patients were confined to bed when first seen, owing to the severity of the attacks. ephedrine, adrenaline and theophylline with ethylenediamine had been tried either by other doctors or by myself before starting the new treatment which was applied only where these had proved unsatisfactory. Each patient was thoroughly examined and his chest was radiographed, and in each case stools were examined for parasites. In 7 of the 12 cases of asthma no underlying organic case was found.

The patients were submitted to a skin test for sensitivity to procaine, and thereafter were given up to 10 ml. of 1% procaine hydrochloride (without adrenaline) intravenously. Immediately after the injection the patient feels light-headed—a sensation which lasts for a few minutes and is followed by a sense of relief and well-being. The spasm is much decreased but not totally abolished. He is then given 0.2 g. of 'Neonatergan' by mouth, and the drug is continued in a daily dosage of 1 g. in four divided doses, for a week, after which the dose is gradually reduced to a maintenance level. In only 2 cases was it necessary to give a second injection of procaine, on the day after the first.

In the 7 cases of asthma where no cause was apparent the attacks became mild and infrequent, the remain-

¹ Copley A. L. *Science* 1945 101 436

² See *Lancet* July 15 1950 p 113

² *Bull Soc méd Hôp Paris* 1941 Pr m& 1943

ing cases benefit, though slighter, was still evident. In the 21 cases where the asthma was secondary to bronchitis, this combined treatment gave equally satisfactory results. No ill effects from the procaine injections were noted. Neoantergan in initial doses of 1 g daily was much less satisfactory when given during the attacks, unless these were first arrested with procaine, and with this heavier dosage there were no ill effects apart from slight nausea and "drunkenness."

Kasr-el-Ainy Hospital Cairo

S M TALAAT

CLINICAL PATHOLOGY IN THE N H S

SIR,—No doubt many clinical pathologists will have read Dr Dyke's article of July 15 with satisfaction at seeing their own view expressed so clearly.

Some of his points deserve underlining. His plea, not for extreme centralisation, but for centralisation within the group, or even within a super group made up to two or three groups, is important. A scheme whereby technical personnel may, without difficulty or formality, be transferred for periods from one laboratory to another, so that every technician spends some time at the group or central laboratory, should ensure that techniques are progressive and moderately standardised.

Of even greater moment is the light which Dr Dyke throws upon what is in effect a quiet revolution—namely, the development of a National Service in Clinical Pathology. The value of the service as now conceived is threefold. By enabling general practitioners directly and quickly to obtain simple but important laboratory investigations, and thus establish diagnosis, and, in certain cases, institute and control treatment, it

1 Saves working people's time and health

2 Maintains the practitioner's interest in both his patient and his art. (The tendency was for the former to disappear in hospital, and the latter consequently to languish.)

3 Saves beds

The clinical pathologist should regard it as an important part of his function to collaborate, genuinely and effectively, with the general practitioner. Though domiciliary visit fees are no longer paid, few whole time pathologists will on that account deny their consultative services, which may be helpful to the practitioner and which certainly enliven their own routine bench work.

Dr Dyke's article gives the sort of guidance required for this experiment in a National Clinical Pathology Service.

M. S. SPINK

Public Health

Poliomyelitis

In England and Wales notifications of poliomyelitis in the week ended July 15 numbered paralytic cases 152 (139), non-paralytic cases 60 (73), total 212 (212).

The figures for the previous week are shown in parentheses. With identical total figures for the two weeks, there was an increase of 13 in the paralytic cases offset by a reduction of the same size in the non-paralytic cases.

The disease is still most prevalent in Warwickshire, but notifications there are on the decline as the following figures show.

Week ended	Paralytic	Cases Non-paralytic	Total
June 24	43	2	45
July 1	39	8	47
July 8	37	4	41
July 15	32	6	38

In Lancashire, where there has been some prevalence of the disease, there was a small increase of 6 paralytic cases to a total of 18 and a decrease of 1 in the non-

paralytic type to a total of 4. In Worcester there was a material fall from 18 paralytic and 6 non-paralytic to 10 paralytic and 1 non-paralytic. In London there was a decided fall from 15 to 4 paralytic to 4 non-paralytic cases.

Food-poisoning in co Durham

The outbreak of salmonella infection at F which we described last week (p. 147) is now over. There has been one death, in a woman who had eaten the pork sandwiches. A post-mortem examination has been done, on the coroner's instruction, but the bacteriological findings have not yet been received. The organism has been isolated from the interior of a portion of the infected pig's carcass from its intestinal wall.

The June Quarter

In England and Wales the numbers of both still-births and deaths of children under 1 year of age in the second quarter of this year were the lowest record for any June quarter. There were 4175 still-births giving a rate of 22.5 per 1000 total live and still-births. These figures compare with 4470 and 22.7 in the period a year ago, and 6039 and 38.9 in the June of 1938. Deaths of children under 1 year of age numbered 5026, representing a rate of 28 per 1000 related births. In the second quarter of 1949 there were 5026 giving a rate of 30, while in the same quarter of 1948 there were 8000 with a rate of 50. The number of live births registered was 181,784, giving a rate of 11.1 per 1000 total population, compared with 11.0 in 1948, and 21.9 in 1947.

There were 120,746 deaths registered, giving a rate of 11.1 per 1000 total population, compared with 11.0 in 1948, and 21.9 in 1947.

1 Registrar General's Return for the week ended July 15. Stationery Office. Pp. 20. 6d.

Births, Marriages, and Deaths

BIRTHS

BLOOM—On July 16 the wife of Dr Harold Bloom—a son.
BURY—On July 13 in London the wife of Dr J. D. Bury—a son.
CASERS—On July 12 at Cirencester Glos the wife of Dr A. Casers—a daughter.
HOLLINGS—On July 18 at Warrington Lancs the wife of A. H. Hollings—a son.
ISSERLIS—On July 13 the wife of Dr K. P. Isserlis—a son.
KASSMAN—On July 17 in London the wife of Dr Sheila D. Kassman—a daughter.
KIEFF—On July 13 at Worpleston Surrey the wife of Dr Kieff—a son.
MACCARTHY—On July 13 the wife of Dr Dermot MacCarthy—a son.
NELIGAN—On July 11 at Newcastle upon Tyne the wife of Gerald Neligan—a daughter.
STRUTHERS—On July 15 at Bristol the wife of Dr G. Struthers—a son.
SWEET—On July 19 at Oxford the wife of Dr A. M. Sweet—a son.
THOMAS—On July 6 at Taplow Bucks the wife of Dr Thomas—a daughter.
WENGER—On July 16 at Burslem Staffs the wife of Mr Wenger F. R. C. S.—a daughter.

MARRIAGES

ARTHURTON—EDMONDS—On July 15, at Banstead Surrey William Arthurton M.R.C.P. to Evelyn Florence Edmonds.
FREELAND—EVANS—On July 16 at Ilford Essex, Pa. Freeland B.M. to Patricia Evans.
JOHNSON—OLIVER—On July 15 in London Francis Johnson M.B. to Patricia Eva Oliver.
MAYCOCK—DRSCH—On July 22 in London James Maycock M.B. to Marie Louise Desch.
WATKINSON—VELDHUYZEN—On July 16 in London R. K. Watkinson M.B. to Ellen Veldhuyzen M.B.
WHITE—LOSEBY—On July 8 in Hong Kong Charles C. White B.M. to Diane Jeannette Loseby.
WILSHIRE—WELLS—On July 15, in London Basil Wilshire M.R.C.S. to Anne Wells.

DEATHS

GOLDIE—On July 17 Edward Alexander Marie Joachim M.C. M.B. Lond.
MALAHER—On July 18 at Reading Bruce Malaher L.M.D. R.A.M.C. ret'd aged 62.
PRICE—On July 24 in London Ivor Isaac Price M.B. Lond.
STEVENSON—On July 14 at Cambridge Claude Moberly Stevenson M.D. Camb.
WILLIAMS—On July 17 John Cadwaladr Williams M.D. aged 90.

Notes and News

ROYAL MEDICAL BENEVOLENT FUND

Annual general meeting, held on July 11, Lord Hanson was re-elected president, Dr C Luther hon treasurer, and Mr Victor Riddell hon secretary. In producing his report for 1949, said that he had been able to distribute £37,202, which was more than in any previous year and left a deficit of £3, £4, or even £5 a week. Some of those thus were members of the medical profession, old and with none to care for them, who needed large grants for domestic or nursing care, others were elderly widows who were in great distress, and young widows who needed to educate and maintain children. Ranked especially those subscribers who had responded to appeals to sign a seven year deed of covenant for the Fund showed £5333 income tax recovered under deeds of covenant. The Fund includes one year's claim and also part of another. "Once more," he said, "I ask all those who have not yet set their signature to a deed to communicate at once to the office (1, Balliol House, Manor Fields, London, N 1) who will send the necessary paper for signature. It is not that the deed is signed does not mean that it costs more, but it does mean that it benefits them in being able to reclaim income tax." Various ways in which the Fund could be helped and the office work done were (a) by using a banker's order (the Fund's bank is Westminster Bank, Hanover Square, W 1), (b) by sending cheques early in the year, (c) by signing a year covenant, and (d) by remembering the Fund in their will—taking care to give its correct title and address.

THE VIM SYRINGE

Messrs Henry Milward & Sons have lately sent us one of their latest 20 ml "Vim" syringes, through their agents Messrs Chas F Thackray Ltd. This is of the glass and metal type having a ground glass plunger but a metal nozzle attached to the glass barrel with a high melting point cement. The features of this syringe are sturdy construction, excellent plunger to barrel, clear graduations (in ml) which are visible into the glass and are therefore presumably permanent. The provision of a "luer" mount—in this instance fitted with a rubber stopper. It would be a great advantage if the luer mount were used for all syringes, since it is robust and its bore is suited for the transmission of viscous fluids. Manufacturers have incorporated a flat surface on the barrel at the end of the syringe barrel, to prevent it from rolling on an inclined surface. The only point to criticise is the clumsy wire attachment which is supposed to prevent the plunger from falling out of the barrel if it should be detached. The syringe can be sterilised by boiling if the barrel is oiled before assembly and the syringe placed in soft water which is then brought to the boil. Alternatively, dry sterilisation can be used, provided that a temperature of 160°C is not exceeded, beyond this temperature the rubber on the attaching nozzle to barrel might melt. It is pleasing to find a British made syringe whose workmanship will stand comparison with that of any similar foreign product.

COUNTRY DOCTOR

The Country Doctor a film strip devised by Dr Stephen Hadfield, but pictorially a typical day in a country doctor's life. The film strip together with the script that accompanies it is of especial use for showing to older school children. It has been produced as one of the "Men at Work" series, by the Common Ground Ltd. Sydney Place, London, S W 7.

University of Manchester

Part 2 of the examination for the D.P.M., J T Leyberg Alfred Model have been successful. Dr F C Wilkinson is retiring from the chair of dental surgery, and the deanship of the dental school on Nov 1.

University of Leeds

A F Maloney has been appointed to the new post of lecturer in neuropathology. Dr B W Wyke has been appointed lecturer in physiology, and Dr R N Tattersall lecturer in medicine.

University of Oxford

In a congregation on July 15, the following degrees were conferred:

D.M.—W D Brinton
B.M.—D J Goldsmid C N Watson J D Cairns G C R Morris
John Taylor J G Armstrong J M L Gilks G E D Morrall
W W Slack W A Openshaw J R W Gleave, R F Brown
M J Evans J L Galbraith Margaret E H Warwick Margery P S Woolf *M J Rosenthal *Jen M Shanks, *Anne S Fowkes
*In absentia

On July 25, the honorary degree of D.C.L. was conferred on Viscount Addison, M.D., and the honorary degree of D.Sc. on Prof G W Corner, M.D.

University of London

The following have been successful in recent examinations
D.M.R.D.—W E Craddock Joan M T MacCarthy William Smith W R R Thursfield C D Wilson Sharp
D.M.R.F.—L W Emery Frances A Fouracres Basil Strickland

Dr E R Boland has been elected dean of the faculty of medicine for 1950-52.

The title of professor emeritus of surgery has been conferred on Prof C A Pannett, on his retirement from the chair of surgery at St Mary's Hospital Medical School, which he has held since 1922.

The title of professor emeritus of obstetrics and gynaecology has been conferred on Prof James Young, on his retirement from the chair of obstetrics and gynaecology at the Post-graduate Medical School of London, which he has held since 1934.

University of Birmingham

On July 1 the honorary degree of doctor of science was conferred on Dr Leonard Colebrook, F.R.S., and on Prof H M Evans (University of California). The following degrees were also conferred:

M.D.—R G Record (with honours) C R Lowe A G W Whitfield

M.Ch.—C P Nicholas

Ph.D.—C N Hland

Royal College of Physicians of Edinburgh

At a meeting of the college held on July 18, with Dr W A Alexander, the vice president, in the chair, the following were elected fellows:

Kalla K V Rao, R L Langley, E L Thomson.

The following were elected members:

John Gillies, J B Caylor, G I H Bralme, Zbigniew Godlowski, R P Leake, D R Huglins, Leonard Crome, I S Meredith, A T M Myers, B F H Koch, R W B Scott, Betty E A Magill, R J Cuthbert, Nan Wan Low, Ding N Banerjee, R L Amols, R A Burston, J McC Murdoch, E V C Dawson, R C W Lowe, A D Muir, L S Smith, R W Morris, Mary Patten, Isaac Cohen.

Mr Leonard Jolley, librarian of the Selly Oak Colleges, Birmingham, has been appointed librarian of the college in succession to Mr T H Graham, who has retired.

Royal College of Surgeons of Edinburgh

At a meeting on July 19, with Mr W Quarry Wood, the president, in the chair, the following were admitted fellows:

S O Awollyi, A S Badger, A N Cameron, Lazar Ganz, S P Jain, F R C Johnston, N R Mackay, K G Macdonald, J R Moffat, R F Mulligan, J G Murray, K K Murthy, J A O'Carra, E H Rees, W A T Robb, D I Roberts, Kenneth Roston, Edward Sarfaty, J H S Scott, Harmel Singh, J J W, van Zyl, S P Wanchoo, I B Watson, R B C Welsh.

Royal Society of Medicine

The council of this society has decided to create a section of general practice, which "will concern itself solely with additions to and applications of medical knowledge under the conditions of general practice," and "will strictly avoid any suspicion that its discussions embrace any matters concerned with the political and ethical aspects of the technical and scientific aspects of general medical practice." If within three months no objections are received from fellows, the new section will ipso facto be established.

Harveian Society of London

The summer meeting of this society was held on July 19, at the Papworth Village Settlement, where Dr R R Trail, medical director of the settlement and president of the society, explained the principles on which Papworth worked. There were, he said, three main objects—active treatment, rehabilitation, and resettlement. He pointed out that no child born at Papworth during the 32 years of its existence had developed pulmonary tuberculosis. Visits were paid to the X-ray department, where demonstrations were given, and to the industries where patients were seen at work making leather goods, furniture and motor car bodies and engaged in printing and book binding.

Edinburgh Post-Graduate Board for Medicine

On Monday, July 31, at 3.30 p.m. in the anatomy theatre of Edinburgh University, Dr A J Rhodes, on Polomyelitis and Poliomyelitis like illnesses.

British Medical Association Prizes

The Sir Charles Hastings clinical prize (50 £) offered by the association for an essay, by a member, in general practice, which "must include personal observations and experiences collected by the candidate in practice." The Charles Oliver Hawthorne clinical prize be awarded as a second prize. Inquiries should be made to the secretary of the association, B.M.A. House, 11 Square, London, W.C.1.

Weekend Course on Rheumatic Diseases

A weekend course on the chronic rheumatic diseases to be held at the rheumatism unit of St Stephen's Hospital, London, S.W.10, on Saturday and Sunday, Oct 1-2. The course will be opened by Lord Amulree, who will discuss the social and economic aspects.

Institute of Ophthalmology

On Oct 4 Dr Russell Brain, F.R.C.P., will deliver the inaugural address of the new session at 4.30 p.m. at the institute, Judd Street, London, W.C.1. The annual meeting of the institute will be held the same evening at 7.30 at Claridges Hotel. To both of these functions past and present members of the institute and of Moorfields Westminster and City Eye Hospital are invited. Tickets for the dinner (5 £) be had from the secretary of the institute.

Royal Appointment

Surgeon Captain G F Abercrombie has been appointed an honorary physician to the King in succession to Sir Captain C C Elliott.

B Sc, M B Manc

HOLOGIST, ALDER HEY CHILDREN'S HOSPITAL, LIVERPOOL

WILLIAM COACKLEY

F I M L T

in the Department of Child Health University of Liverpool,
and Alder Hey Children's Hospital

In 1945 the association of a particular serological
type of *Bacterium coli* (var *neapolitanum*) with infantile
gastro-enteritis was noted (Bray 1945, Bray and Bevan
1945). Similar observations have since been made by
Sangster (1948), Giles et al (1949), Holzel et al
(1949), and Taylor et al (1949), the last authors calling
the strain *Bact coli* D 433. Our purpose here is to
describe two outbreaks of neonatal diarrhoea and vomiting
of different clinical types. One was associated with a
strain of *Bact coli* serologically identical with that
mentioned above, and we shall refer to it as *Bact coli*
433.

During a long term investigation of cases of infantile
gastro-enteritis admitted to Alder Hey Children's
Hospital, in which special attention was being paid to
the occurrence of *Bact coli* D 433, it was noted that a
severe case, with this organism in the stools, had been
admitted within five days of discharge from a Liverpool
maternity unit (A). When this unit was visited by one
of us (A C K) on Feb. 24, 1949 2 babies in the premature
unit were found to be ill with diarrhoea and vomiting
which had been attributed to parenteral infection, though
no local focus could be found. Rectal swabs from
these two infants gave profuse growths of *Bact coli*
433, and we therefore decided to make detailed
investigations.

Maternity Unit A consists of the main block (approx-
imately 100 beds) and the premature unit (12 cots),
separated by approximately 150 yards of open ground.
In the main block normal newborn infants are kept in
wards at the foot of the beds of their respective mothers in
three wards of 25 beds each. Attached to the wards is
a large nursery to which these infants are taken for
feeding and weighing—procedures usually though not
always carried out by the nurses from the babies' own
wards. Infants who are immature, who are suffering from
minor infections, birth injuries and other abnormalities,
who require test weighing, and infants whose mothers
are ill, are kept in the nursery. Babies with minor
infections are separated from the rest in one corner. The
nursery has its own nursing staff, but its nurses not
infrequently assisted in bathing and weighing the normal
infants from the wards.

Leading from the nursery is a corridor on to which
open the feed kitchen and four separate cells each
containing one cot, where infants suffering from more
serious infections are nursed. So far as possible the duty
nursing these infants was discharged by a nurse who
did not come into contact with any other babies, though
distressing sometimes made this impossible.
As soon as the outbreak of infection was recognised
it was decided that normal babies should be bathed and
weighed in their respective wards, and those infants who
could normally have been put in the nursery were left
with their mothers. Thus the number of infants in the
nursery was kept at a minimum until there was no
evidence of new cases occurring. For one week only,

admission to the maternity unit was limited to abnormal
obstetric cases requiring expert care.

The premature unit, which has its own nursing staff
and feed kitchen, consists of two wards, of 6 and 4 cots,
and two rooms containing 1 cot each. It was the practice
to keep the premature infants in the main nursery for
twelve to twenty four hours before transferring them to
the premature unit. For three weeks after the outbreak
of gastro-enteritis was recognised this transfer of
prematures was suspended.

COURSE OF THE INVESTIGATION

The investigation developed along the following lines.

1 Infants in whom diarrhoea and vomiting was
suspected or had developed were isolated as far as
practicable and rectal swabs were taken immediately.

2 All infants in the maternity unit had rectal swabs
taken. As the first 2 suspicious cases had been found in
the premature unit, all in that unit were swabbed
immediately, and thereafter every seven days. During
the first week, in addition to any showing suspicious
features, all who were for discharge from the main
block were swabbed on the day of leaving. From the
eighth to the eleventh days, inclusive, of the epidemic,
specimens were taken from every infant in the main
block. Swabbing of infants on discharge, and of suspicious
cases, continued daily for a further fourteen days after
this.

3 All hospitals in the city to which cases of infantile
diarrhoea and vomiting are admitted were asked to inform
us of the admission of any infants who had recently been
discharged from Maternity Unit A. This arrangement
was continued for several weeks after the outbreak had
apparently ceased.

4 Further observations were made on the following
groups of infants who were apparently well on discharge
from the maternity unit.

(a) The 12 who had rectal swabs positive for *Bact coli*
D 433 on discharge.

(b) A group of 43 selected at random from those discharged
with rectal swabs negative for *Bact coli* D 433. Of these,
25 had a further bacteriological and clinical examination. Of
the remainder 13 who did not attend were contacted by letter
or through the maternity and child welfare service. The
remaining 5 could not be traced.

(c) A second group of 28 also selected at random from those
bacterologically negative on discharge, was followed up by
letter. Of these we failed to trace 4 only.

(d) The 2 infants at risk in the premature unit who were
discharged well and bacterologically negative.

A decision that the infants in (b), (c), and (d) were unlikely
to develop diarrhoea and vomiting was not made until
they had been discharged from the unit at least fourteen
days. This period of fourteen days was taken since it
was thought probable that it was the maximum incuba-
tion period of the disease, and that diarrhoea and vomiting
later than this was therefore unlikely to be due to
infection acquired in the maternity unit. In actual fact
all the infants in these groups remained well for at least
a month.

5 All infants in the maternity unit nine weeks after
the beginning of the outbreak had rectal swabs taken.
No further cases had occurred in the unit during the
previous five and a half weeks.

6 Another Liverpool maternity unit (B) of about 100
beds, in which no cases of diarrhoea and vomiting had
been noted over a long period was investigated bacterio-
logically during the intervening time. In this survey
191 infants were examined.

INCIDENCE OF DISEASE AND *Bact coli* D 433 IN MATERNITY UNIT A

From the time the first cases of neonatal diarrhoea
and vomiting were recognised in Maternity Unit A,

Incidence of diarrhoea and vomiting showing ages of affected infants at dates of onset.

- 10 = Age in days on day of onset
 • Date of onset after discharge
 ○ Date of onset in Main Block
 X Date of onset in Premature Unit

until the first part of the investigation was completed three weeks later, the total number of infants at risk was 144. 12 of these were in the premature unit and 10 of them became ill. Of the 132 in the main block, 7 became ill.

Premature Unit

At the time the first 2 infants in the premature unit were found to be sick there were 7 others at risk, and during the next five days 3 more were admitted, making a total of 12. The accompanying chart shows the dates of the onset of illness in this group. As all these infants had spent twelve to twenty four hours in the nursery of the main block before being transferred to the premature unit, it is possible that the infection was contracted in the main block. But it is equally likely that one or more of the early cases was infected in the main block and carried the infection into the premature unit. It will be seen from the chart that cases occurred at a fairly regular rate until March 12, by which date the 2 babies who remained well had been discharged. A profuse growth of *Bact coli* D 433 was obtained from all the 10 infants who developed diarrhoea and vomiting. The 2 who remained well were both negative.

As the infants were swabbed only at intervals of approximately seven days, accurate correlation between the onset of the disease and the time at which the stools

became positive for *Bact coli* D 433 is not. However, as indicated in table I, 6 were found at intervals varying from one to six days after. Further positive swabs were obtained in all these. Of these 6, 3 had been swabbed previously and negative, the interval between swabbing and the onset of disease being seven days in 2 cases and eight days in the other. The remaining 4 were all found positive days before the onset of diarrhoea and vomiting.

The 2 infants who remained well spent sixteen and twelve days in the unit. Two rectal swabs were taken from each and all were negative for *Bact coli* D 433. The last were taken three days before discharge and the day of discharge respectively.

The Main Block

During the investigation 7 infants in the main block became ill, all having been in the nursery from birth. Of these cases 4 occurred between Feb 26 and March 11 when the nursery was closed to further admissions. The other 3 occurred between March 8 and 18 after which no infants remained who were not already ill. Between Feb 26 and March 18, 28 infants had been at risk in the nursery. None who had been nursed in the ward with their mothers during this period became ill while in hospital.

Rectal swabs, taken after the start of symptoms (table II) from all the 7 infants who became ill in the nursery, were positive for *Bact coli* D 433. Of these only 2 had been swabbed previously and these had been found negative one day and seven days before the illness.

TABLE II—SICK INFANTS NURSED IN NURSERY OF MAIN BLOCK. RESULTS OF EXAMINATION OF RECTAL SWABS FOR *Bact coli* D 433 IN RELATION TO ONSET OF ILLNESS

Case no	Age at onset of illness (days)	Result of swab before onset		First swab after onset

16	4	-1	Neg	Day illness started	Pos
19	10	-7	Neg		

*Days counted from day of onset of illness reckoned as 0

On discharge 12 healthy babies (8 in the nursery and 4 in the wards) had positive rectal swabs, but, as will be shown later, 7 of these became ill at home. Negative rectal swabs were obtained on discharge from 11 infants who had remained well, 58 of them had been swabbed twice. Of the 112, 107 were finally swabbed the day of discharge and 5 at intervals up to five days before discharge (Mean age 10.7 days, range 4.5 days). No growth was obtained from the swab of either infant at discharge (see below).

INCIDENCE OF DISEASE AND *Bact coli* D 433 AT DISCHARGE FROM MATERNITY UNIT A

Of the 12 infants discharged with rectal swabs positive for *Bact coli* D 433, 7 became ill within nine days; all but 1, who died at home three days after discharge, were reswabbed and again found positive. The other 5 remained well during the follow up period.

Two infants who had been discharged from the nursery of the main block before the start of the investigation became ill at home and were admitted to Hey Children's Hospital, where rectal swabs, taken within ten minutes of admission, were positive for *Bact coli* D 433.

Of the 62 infants contacted personally or by letter 25 had rectal swabs taken on attendance at the

a period between four and thirty four days (16 the tenth day) after discharge. Of these, 2 had a positive, but neither they nor the other 23 ped any signs of illness. The twin (case 29) of one 2 positive infants was ill with diarrhoea and ng and was admitted to Alder Hey Children's tal where he was found to be positive for *Bact coli* 3. His swab on discharge was the one which had

III—NUMBER, DISTRIBUTION, AND MORTALITY OF CASES

ult	Sick in main block	Sick in premature unit	Sick after discharge	Total
ered	3	5	5	13 (43.5%)
rown	4	5	7	16 (53.5%)
al	—	—	1	1 (3.0%)
	7	10	13	30 (100.0%)

aced no growth and he had not been included in the ifants selected at random. None of the remaining the control group developed any illness.

the group of 51 infants who were not followed up, re admitted to hospital with diarrhoea and vomiting within eight days of discharge from the maternity.

Of these, 2 were admitted to Alder Hey Children's pital (cases 20 and 29), and rectal swabs taken immedi y after admission were positive. The other 2 (cases and 25) were admitted to an isolation hospital in city, and rectal swabs taken one and three days ectively after admission were also positive.*

hough it is possible that several others discharged ative for *Bact coli* D 433 might have become positive, hink it unlikely that any admitted to hospital's gastro enteritis were missed. Furthermore, in the up that we could not follow up, 4 (out of 51) became which is a higher proportion than was found in the trol group (none out of 62).

o summarise. Of the total of 37 infants who were nd to have rectal swabs positive for *Bact coli* D 433 ring this part of the investigation, 30 became ill ble in) and none of those with negative swabs did so. e 62 infants picked at random from the 112 discharged h negative rectal swabs remained well for at least uiteen days after discharge. Of these 62, 25 had further tal swabs taken, 2 were found to be positive but ther of these infants became ill. Of the remaining 50 o were negative on discharge, 3 became ill and were nitted to hospital where they were then found to e rectal swabs positive for *Bact coli* D 433. One unt with no growth on discharge later became ill and ; found to be positive also. The 2 who did not develop rrhoea and vomiting while in the premature unit aimed well after discharge.

VEY OF INCIDENCE OF *Bact coli* D 433 IN MATERNITY UNIT B

uring a period of four weeks, 210 rectal swabs were ,an from 191 infants (Mean age 7.4 days range 4 days). Of these, 4 infants in different wards were nd to be positive. They developed no illness while in pital nor during a fourteen day follow up. There : no gastro enteritis in this unit either during, or for month before and after, the swabbing. everal months before, there had been sporadic bbing of newborn infants in this maternity unit. infants (mean age 8.2 days range 4-18 days) had a swabbed, and none had been positive. There was iarrhoea or vomiting in the unit.

*bles summarising the particulars of each case have been multi graphed and are obtainable on application to THE LANCET Office 7, Adam Street, London W.C.2

SURVEY OF INCIDENCE OF *Bact coli* D 433 IN MATERNITY UNIT A AFTER A DISEASE FREE INTERVAL

All the 55 infants in the main block five and a half weeks after the last case of diarrhoea and vomiting had occurred in the unit were swabbed. (Mean age 6.9 days range 1-23 days). All were negative for *Bact coli* D 433. At the same time the babies in the premature unit were swabbed. Of the 11 infants in the unit at the start, 5 who had been kept there for twenty six days or more were positive. During the following seven weeks the infants in the unit were reswabbed twelve times. 4 others became positive before the organism finally dis appeared, two and a half weeks after swabbing was resumed. The total number swabbed in this period was 25 and all remained well while in the unit and for fourteen days after discharge.

FEEDING AND INFECTION

Of the 144 infants ill or at risk during the investigation, 110 were fully breast fed except for small amounts of glucose saline during the first twenty four hours, in the remainder the child was fed partly or entirely on pooled expressed breast milk or dried milk (table iv(a)). Of the breast fed, only 5 (4.5%) became ill, whereas 23 (68%) of the 34 who did not receive their feeds directly from their own mothers developed diarrhoea and vomiting.

Of the 28 infants in the nursery (table iv(b)), 11 were fully breast fed and only 3 (27%) became sick, but of the 17 who were fed by other methods, 11 (65%) developed the illness. It should be noted that 13 (82%) of the latter

TABLE IV—INFECTION IN RELATION TO METHOD OF FEEDING

Feeding method	Total	Well	Sick	<i>Bact coli</i> D 433 positive
(a) Complete Maternity Unit A

Other methods*	34	32.2%	67.8%	77.0%
(b) Main Block Nursery				
Breast fed	11	72.5%	27.5%	45.5%
Other methods	17	35.3%	64.7%	82.5%

*Breast milk plus dried milk 14 breast milk plus expressed breast milk 7 dried milk 5 expressed breast milk 8

group became positive for *Bact coli* D 433, but only (45%) of those fed directly from the breast.

CLINICAL FEATURES

Of the 30 infants who became ill, 14 were 5 lb 8 oz or under at birth, and only 6 of these were fed directly from the breast. The clinical picture varied from that of a mild illness, with little constitutional disturbance, to an illness of great severity. Of the moderately severe or severe cases in which the child neither died nor was treated with aerosporin, the average duration was twelve days (shortest eight and longest twenty five days). The characteristic first symptom was an unexplained failure to gain weight, or even a loss of weight. Each of the 17 infants who developed the disease while in Maternity Unit A lost weight, either continuously from birth, or for one to five days before the onset of diarrhoea and vomiting. Reluctance to feed was noted in 11 of the 17 infants before diarrhoea and vomiting commenced, but all had anorexia once the disease was fully developed.

Diarrhoea and vomiting started simultaneously in 11 cases diarrhoea preceded the vomiting by twelve to twenty four hours in 11 and vomiting came first in 8. The stools, which were generally watery, varied in colour from bright yellow to green, the presence of mucus was fairly constant. A seminal smell was common but not invariable (Beavan 1944). In the severe cases dehydration

developed rapidly, and sometimes it preceded diarrhœa and vomiting. All the severe cases became listless and apathetic, with greyish pallor, early in the illness—more so than could be accounted for by dehydration alone. These features were regarded as a "toxic" manifestation. Pyrexia was inconstant.

When the infants received intravenous therapy they usually showed considerable improvement, but they tended to relapse when again given milk by mouth, they became reluctant to take a feed and their vomiting and diarrhœa, with dehydration, recurred. Reluctance to feed was deemed a significant prognostic feature for two reasons: (1) that so long as it persisted there was a definite risk of relapse, indicating that the disease process was continuing even if diarrhœa and vomiting had abated, and (2) that its cessation—usually suddenly in twelve hours or so—was an almost certain sign that the illness had run its course and that the infant had entered the convalescent phase. It will be shown in a later paper that in infantile (including neonatal) gastro-enteritis a "toxic" appearance, a tendency to relapse, and a reluctance to feed have been almost always associated with the presence of *Bact. coli* D 433 in the stools, they were rarely found in cases of diarrhœa and vomiting from which this strain was not isolated.

Evidence of a local infection was present at the onset in 7 infants (umbilical sepsis 1, ophthalmia 1, paronychia 1, and oral thrush 4). A secondary infection occurred during the course of the illness in 7 cases (thrombophlebitis of veins used for intravenous therapy 4, acute suppurative otitis media 2, mastoiditis 1, and paronychia 1). One infant developed a hemorrhagic tendency which ceased when 'Synkavit' was given. Of the 30 infants who became ill, 13 are known to have died (43%), of the 14 premature infants (4 were in the main block nursery), 50% died, and of the 15 who were full term, 40% died. The remaining infant, whose ultimate fate is unknown, was sufficiently ill for intravenous therapy to be thought necessary, but his mother refused hospital treatment and we failed to make further contact.

There is little difference between the death rates of the mature and premature infants in this series. Aerosporin was given to 7 infants. 2 died but the other 5, who received it two to twelve days after the onset of diarrhœa and vomiting, showed striking improvement within twenty-four hours. Of the 13 fatal cases death was attributed directly to gastro-enteritis in 8 and to secondary infection as a complication of gastro-enteritis in 3. The complications were as follows: aspiration bronchopneumonia and septicæmia 1, mastoiditis 1, and septicæmia following thrombophlebitis 1. The other 2 infants died suddenly after aspiration of a feed or vomit.

There was no significant illness in the mothers or staff during the course of the outbreak.

PATHOLOGICAL FINDINGS

Necropsy was performed by us on 5 of the 13 infants who died (cases 2, 4, 14, 22, and 24). In 4 cases no gross change was found in the intestine, apart from mucosal congestion, but in the 5th case (no. 22), where there had been much abdominal distension before death, the small intestine (especially the ileum) was grossly dilated, the mucosa showing many areas of necrosis and hemorrhage, with numerous gas vesicles in the submucosa and muscularis.

Bact. coli D 433 was isolated from stomach and intestine in 4 of these cases, the negative one had ceased to have diarrhœa and vomiting two days before death, but had developed a thrombophlebitis and septicæmia, and had aspirated regurgitated stomach contents into the lungs. Mesenteric lymph nodes were either normal or slightly enlarged and congested. The middle ear clefts

were abnormal in only 1 case (no. 24), both cavities contained pus from which *Streptococcus* and *Bact. coli* D 433 were isolated. The livers were normal macroscopically, microscopic examination limited to slight congestion and (in 1 case) slight portal lymphocytic infiltration. It has often been noted that since plasma and protein hydrolysates have been used in the treatment of infantile gastro-enteritis, fatty infiltration of the liver has been found commonly. Changes in the brain were limited to congestion of the pia arachnoid vessels and oedema of meninges. There was no evidence of lesions like those described by Christensen and Biering-Sørensen (1949).

SECOND OUTBREAK OF DIARRHŒA AND VOMITING IN MATERNITY UNIT A

During September and October, 1949, another outbreak of neonatal diarrhœa and vomiting occurred in Maternity Unit A, but it was remarkably different.

TABLE V—PRINCIPAL FEATURES OF THE TWO EPIDEMICS

Features	1st epidemic	2nd epidemic
Fully breast fed	20.0%	50.0%
Initial weight loss or failure to gain	100.0%	100.0%
Diarrhœa	100.0%	100.0%
Vomiting	90.0%	15.3%
Anorexia	90.0%	14.3%
Toxic appearance	90.0%	4.8%
Relapse	Very common	None
Average duration of illness	10 days	5 days
Mortality rate	43.0%	0.0%
<i>Bact. coli</i> D 433 in stools	100.0%	0.0%

the previous one (table V). There were 16 cases and 0 deaths.

As in the first outbreak, the presenting symptom was an unexplained failure to gain weight, or an actual loss. This was followed after a day or so by the passage of relaxed or watery stools, occasionally but not often with mild vomiting. The diarrhœa lasted for two to three days, and only in 2 cases for as long as five days. All infants remained bright throughout and never looked "toxic", only 2 were reluctant to take feeds and these caused no anxiety. Intravenous therapy was required by 4 babies for one to two days, after which they made satisfactory progress. Of the remaining 12, 3 were able to continue normal feeding. After this, glucose saline by mouth for twenty-four hours and then diluted expressed breast milk, caused rapid gains in weight, it was common to see an increase of 10–12 oz. in five days. Only 2 infants were slow to respond. The average duration of the illness was five days and no case relapsed.

Rectal swabs were taken from 12 of the 16 infants in the illness, and *Bact. coli* D 433 was never isolated. There was no notable illness of any sort in the mothers at the time. In contrast with the first epidemic, breast-fed babies (8) were affected as often as artificially fed.

PATHOGENICITY OF *Bact. coli* D 433 IN ADULTS

Two experiments were undertaken with adult volunteers who had not handled *Bact. coli* D 433. The one used had been isolated eleven months previously from a severe case of infantile gastro-enteritis and had been used for the preparation of the agglutinating medium employed throughout the investigation. We had subcultures derived in different ways: strain A, taken from subcultures kept for long intervals on plates at room temperature, while strain B was a recent subculture of the refrigerated agar slope culture.

Before ingestion, all strains were grown for three days subculturing each day, in 0.05% agar, incubated at 37°C in 10% CO₂. The dose administered in 0.2 ml.

agar was approximately 2000×10^6 organisms in eighteen hour culture

Experiment

Volunteers were divided into three equal groups

- i were given a dose of strain A
- ii were given a dose of strain B
- iii (controls) were given a similar volume of dated incubated medium

In case the dose was given in milk one to two hours much and the volunteers were kept in ignorance of grouping. Of group i, 2 suffered mild abdominal fort late the same evening, 1 having several loose, but on the following morning all 3 had diarrhoea abdominal discomfort, the stools numbering from 8 to 10. There was mild anorexia but no vomiting. Symptoms abated during the afternoon and the volunteers were back to normal next day. The faeces of all volunteers showed profuse growths of *Bact coli* 120 hours after taking the culture, and 2 were positive on the next day, the last positive in this (i) was at four days. None of group ii developed symptoms. 2 had positive swabs four days after the but not thereafter. The control group (iii) was negative throughout.

Agglutination tests were performed in each with sera from all the subjects, against living and 1 suspensions of *Bact coli* D 433, and again two weeks later with serum from those that were ill. In all cases the titre was less than 1 in 10.

2d Experiment

The second experiment was on similar lines but used different persons. Strain A was taken by 3 volunteers the other 6 took two different strains of typical *Bact coli* that did not show any serological or chemical relationship to *Bact coli* D 433. Of the 3 took strain A, 1 was ill, the symptoms resembling those in the first experiment but with vomiting in addition. The other 2 and the 6 controls remained healthy well.

Because of the shortage of suitable volunteers we were unable to amplify these experiments, but we are investigating possible differences between strains A and B.

DISCUSSION

The term neonatal diarrhoea and vomiting is applied to a number of syndromes differing in their clinical manifestations and probable aetiology. A review of the literature suggests that there are at least six main groups.

Outbreaks due to accepted pathogens such as dysentery or salmonella organisms. Epidemics in which the mortality-rate is high, and the spread of the disease rapid, among the infants at risk, but adults are unaffected. The clinical picture in these outbreaks has been remarkably similar—namely, pronounced loss of weight, anorexia, toxæmia, diarrhoea and vomiting, severe dehydration, and a tendency to relapse (Craig 1930, Frant and Abramson 1938, 1947, Ormiston 1941, Sakula 1943, Gardner 1945, Stern 1947). Our first outbreak seems to fall into this group.

Outbreaks in which diarrhoea is the dominant symptom and vomiting is uncommon. In these the infants rarely appear ill, there is no toxæmia, anorexia, or tendency to relapse, and intravenous therapy is seldom required (Baker 1930, Lembcke et al 1943). Our second outbreak belongs to this group. Those in which diarrhoea has also affected adults. In the outbreak described by Ensign and Hunter (1946) there was a high mortality-rate in the newborn, and *Pseudomonas aeruginosa* was implicated. The outbreak reported by Brown et al (1945) also affected adults, but the disease was mild, with a low mortality-rate in the infants, a virus infection was suspected.

Epidemics of neonatal diarrhoea and vomiting associated with an influenzal type of illness in the

mothers and nursery staff (Lyons and Folsom 1941). The outbreak of this nature described by Colvin and Emory (1941) had a high mortality rate among the infants, and necropsies on them revealed hæmorrhagic pneumonia.

- 6 The outbreaks investigated by Buddingh and Dodd (1944) also involved adults as well as the newborn infants and there was stomatitis, of characteristic type, besides the diarrhoea. These authors produced experimental evidence suggesting that a virus was responsible.

The bacteriological findings in group 2 have been diverse. A large number of organisms have been implicated but in most of these epidemics the bacteriological examination of patients, and especially of contacts and controls, has been inadequate. In at least one group of outbreaks, however, strong evidence of virus aetiology has been produced (Light and Hodes 1943, 1949). In the outbreaks described by Giles and Sangster (1948) and Taylor et al (1949), a close association between the illness and *Bact coli* D 433 in the stools was demonstrated.

Early in our investigation of the association of *Bact coli* D 433 with cases of infantile diarrhoea and vomiting admitted to Alder Hey Children's Hospital it became apparent that the severe and toxic type of case, with its liability to relapse, rarely occurred without *Bact coli* D 433 being present in the stools. This did not hold true for other clinical types of diarrhoea and vomiting, and in fact severe diarrhoea and vomiting which responded rapidly and permanently to intravenous therapy within two days was uncommonly associated with this strain. In other words, a clinical syndrome which can be recognised as a separate entity (whether parenteral infection is present or not) had a very close association with *Bact coli* D 433. The clinical picture of the severe cases encountered in our first epidemic, and, for the most part, of those discussed in group 2, is similar to this.

In our first epidemic all the 30 cases were associated with *Bact coli* D 433 and none of the 109 infants who remained negative developed diarrhoea or vomiting. It is notable that only the 2 healthy babies in the premature unit were negative, and that the 10 ill babies were all positive. It is true that 7 infants who were infected with the strain never became ill, but, even if we assume that the total number of symptomless positives was twice as large, the ratio of sick to well (though positive for *Bact coli* D 433), would be 2:1 which is by no means an unusual finding in salmonella outbreaks. Thus Irvine and Galvin (1949) found during an outbreak of paratyphoid fever that of 13 persons infected with *S. paratyphi* B 6 never developed symptoms of the disease, and Rubbo (1948), investigating an outbreak of infantile gastro enteritis due to *S. derby*, found 21 apparently healthy carriers to 47 clinical cases.

It seems unlikely that *Bact coli* D 433 is a normal commensal in the neonatal or infant population as a whole for Taylor et al (1949) could not find it in 79 healthy non-contact newborn babies, and we found it only 4 times in 224. Similarly, investigating healthy non-contact infants under the age of one year, Giles et al (1949) and Taylor et al (1949) have between them found this organism in less than 2% of approximately 370 infants and we failed to isolate the strain from the rectal swabs of over 380. It might be argued that *Bact coli* D 433 was a commensal in the unit at the time of the outbreak, but, if this was so and if 100% of the sick infants carried the strain, far more than 6% of the remainder should also have been carrying it. It could also be postulated that the organisms existed in small numbers in the guts of healthy infants, and that they were excreted in numbers sufficient for recognition only when diarrhoea started, but profuse growths of the strain were obtained from the rectal swabs of the 11 infants examined.

before any diarrhoea (table I) had occurred. Furthermore, the strain was never found, even in small numbers, during the second outbreak, and as stated in the bacteriological appendix we were able to recognise, on primary plates, scanty numbers of colonies likely to be *Bact coli* D 433 among large numbers of *Bact coli* colonies which were not of this serological type.

We regard these facts as circumstantial evidence that *Bact coli* D 433 was not only closely associated with diarrhoea and vomiting in the first epidemic but was probably responsible for it, either alone or in close symbiosis with some other agent. It should, however, be noted that during the postepidemic period, when the babies in the premature unit were repeatedly swabbed, 9 of the 25 in the unit became positive for varying periods without any sign of illness. It might therefore be suggested that the disease was caused by an intimate symbiosis between *Bact coli* D 433 and some other agent, which was eliminated in the postepidemic period. But in other outbreaks where *Bact coli* D 433 was found there has been no evidence of an associated bacterium or virus (Giles and Sangster 1948, Taylor et al 1949). We are not in a position to confirm these findings, apart from noting the complete absence of salmonellae and shigellae, and a lack of correlation between the disease and organisms of the paracolon group. Though experimental evidence is scanty, it has often been suggested that outbreaks of disease are associated with phases of enhanced virulence of the causal organisms (Topley and Wilson 1946). Variation in virulence of a given salmonella strain is discussed, as regards infants, by numerous workers—e.g., Angrist and Molloy (1946), Mackerras and Mackerras (1949), and Mackerras and Pask (1949). Similar variation in virulence might occur with *Bact coli* D 433 or similar strains, and, as Mackerras and Pask (1949) said of salmonellae, "we suspect that pathogenicity is associated either with dosage of infection or, more probably, with selection by passage of virulent mutants."

Our experiments with adult volunteers suggest that this organism may produce diarrhoea when ingested in a dose comparable to that required with *S typhi murium* (Hormaeche et al 1936).

We were unable to study the mode of spread of the organism, but table IV shows a high degree of correlation between diarrhoea and vomiting and the presence of *Bact coli* D 433 on the one hand and methods of feeding (other than breast milk direct from the breast) on the other. Infants fed with expressed breast-milk were just as liable to develop the illness as were those having artificial feeds. The disease did not break out in the wards where the infants were wholly breast fed, even though initially they were bathed and weighed in the nursery and not infrequently by the nursery staff. It can, of course, be argued that infants in the nursery formed a more susceptible population, all being there primarily because they were not completely normal. But as can be seen from table IV(b) the incidence of illness and *Bact coli* D 433 in breast fed infants in the nursery is very much lower than in those partially or entirely fed by other means.

SUMMARY AND CONCLUSIONS

Two outbreaks of neonatal diarrhoea and vomiting are described. In the first, 30 cases were recognised, and *Bact coli* D 433 was recovered from the rectal swabs of all. The case mortality rate was 43%. The second outbreak involved 16 babies without a death.

The clinical syndromes encountered in the two outbreaks were quite different. The one associated with *Bact coli* D 433 was characterised by diarrhoea and vomiting, anorexia, toxæmia, and a liability to relapse, but the outbreak not associated with this organism was of a relatively mild illness with diarrhoea and little

vomiting, no evidence of toxæmia, and no to relapse.

The incidence of the organism in 224 healthy contact newborn controls was less than 2%, and in 350 healthy non contact infants less than one per cent. It was nil.

Ingestion of the organism by adult volunteers caused comparable illness.

It is suggested that the first outbreak was caused by *Bact coli* D 433—possibly in symbiosis with some other agent—and that other epidemics with similar features may well be due to the same serological type of *Bact coli* or a similar one.

The syndrome should be recognisable not only in epidemics but also among the welter of infantile diarrhoea and vomiting treated in a hospital.

We gratefully acknowledge indebtedness to all who helped us, in particular to Prof Norman B Capon, Prof A W Downie for their encouragement and criticism, to Dr H H MacWilliam and Dr F P medical superintendent and paediatrician respectively at hospital where the epidemics occurred, and to Dr Bell (senior assistant medical officer) of maternity and welfare, Liverpool, Dr J F Swan (medical officer, Bootle), Dr J G Hailwood (divisional medical Lancashire), and Dr A B Christie (medical Fazakerley Fever Hospital) for assistance with information about infants discharged from the maternity unit. Dr Taylor and Dr C Giles kindly supplied sera, and cultures the organisms isolated by them.

Especially would we like to express our thanks to nursing staffs of all the hospitals concerned, but for help this work could never have been done.

Bacteriological Appendix

TERMINOLOGY

The sera used in this investigation were prepared from strain of *Bact coli* isolated from a fatal case of infant gastro enteritis in Alder Hey Hospital. This strain (Stockton and "OK" and "O" antisera prepared from it by method of Kauffmann (1944), gave complete reciprocal agglutination with a strain of "*Bact coli* neapolitanum" type supplied by Dr C Giles, and its corresponding antiserum similarly prepared. This organism is said by Giles to be identical with the strain of *Bact coli* neapolitanum by Bray (1945). Though the identical antigenic structure of Stockton and a strain of "*Bact coli* D 433" supplied by Dr Joan Taylor was not established by similar cross agglutination until the investigation was almost completed, we preferred to use this noncommittal term to avoid the use of some "specific serological type of *Bact coli* var neapolitanum". Furthermore we know that other serologically different strains coming within the biochemical definition of *Bact coli* neapolitanum occur, and should they in the future be found to have clinical significance, difficulty with nomenclature would arise.

ISOLATION OF *Bact coli* D 433

All specimens, taken by rectal swab moistened with glucose broth, were plated out as soon as possible on MacConkey agar and desoxycholate-oxitate agar. At the start of this investigation we had decided to give attention to *Bact coli* D 433, and because of limitations, neither microscopy of specimens nor special media, Desoxycholate plates were examined at 18 and 48 hours. Neither lactose fermenting colonies were picked off for examination the number of colonies depending on the type of different colonial forms. MacConkey plates were examined with a hand lens after 18 hours incubation and slide agglutinations were carried out on all types of lactose fermenting colonies using a D 433 "OK" serum. We have been possible on our MacConkey medium to recognise colonies of *Bact coli* D 433 with considerable accuracy after 18 hours' incubation, they are in general of smaller size with a more regular edge a finer texture and a pink colour, than negative colonies. From each plate four colonies were tested including if present, at least two we considered on colonial appearances not to be *Bact coli* D 433. Occasional colonies of the type mentioned

TABLE VI—DISTRIBUTION OF NON-LACTOSE FERMENTING BACILLI IN GROUPS SWABBED

Group	Place and time of swabbing	Cases in which non lactose fermenters were isolated		
		Para colon bacilli	Proteus group	Others

d	Premature unit after outbreak	3	5	0

d negative on slide agglutination, but colonies of other never proved positive
m each plate giving positive or doubtful slide agglutina
a pure culture from two colonies was examined for
ity in 6 hour peptone water culture, for indole pro
on, and for fermentation of sucrose salicin and dulcitol
er slide agglutinations from agar slopes were also
d out Afterwards at least one colony from each
t was examined further biochemically and serologically

SPECIFICITY OF PRIMARY SLIDE AGGLOUTINATION REACTION

177 colonies giving a positive or doubtful primary slide
ion 163 when examined as mentioned above gave the
chemical reactions of *Bact coli* D 433 and a clear-cut slide
tination from an agar slope with the 'OK' serum The
r 14 were negative in both respects In the course of other
: 160 colonies giving a negative primary slide reaction
carried through in the same way all were negative

FURTHER IDENTIFICATION

urther biochemical tests were made on 57 strains—at
l from each infant with a slide positive stool culture
se glucose maltose, and mannitol were fermented,
acid and gas production, within 24 hours Other sugars
more variable raffinose requiring 1-3 days, dulcitol 2-4
sucrose 1-5 days and salicin 2-6 days for fermentation
nite was not changed after 8 days All strains were non
ile citrate and V.P. negative and indole and V.B. positive
he 57 strains were tested by tube agglutination at 37°C
20 hours (a) living against the 'OK' serum, titre 1/640,
(b) after boiling for 2½ hours against the 'O' serum
: 1/5120 All strains were agglutinated to titre by both
Absorption of the 'OK' serum was carried out with
living strains All reduced the titre to less than 1/40,
most the homologous and absorbing strains

PROFUSENESS OF *Bact coli* D 433

n all cases the faecal cultures at the beginning of the
ess showed profuse growths of *Bact coli* D 433 Growth of
organism from swabs taken either before the illness
ted or from the few positive infants who remained well
often as profuse as at the beginning of the illness.

INCIDENCE OF COLIFORM BACILLI

he incidence of coliform bacilli in the rectum of newborn
dren has recently been investigated by McFarlan et al
9) For purposes of comparison the following figures
te only to infants in the age range 3-11 days all fully
st-fed at the time of swabbing

ernity unit during epidemic	98% of 93 infants
ernity unit after epidemic	100% of 44 infants
rol maternity unit	82% of 133 infants.

here was no difference in the isolation rates of coliform
illi during and after the epidemic in Maternity Unit A,
there is a significant difference between the isolation rates
he two units investigated. ($\chi^2=19.5$ n=1, $P<0.001$)
ie of the infants in Maternity Unit A had received
ose saline during the first 24 hours The comparable
res in the series of McFarlan et al (76% of 28 infants)
e well with our control figure of 82% of 133 infants The
erence in incidence of diarrhoea and vomiting between

infants fed directly from the breast and those fed by other
means was not related to the total incidence of coliform
bacilli

INCIDENCE OF NON-LACTOSE FERMENTING COLIFORM BACILLI

No organisms of the salmonella or shigella groups were
isolated during this investigation. Table VI shows the
incidence of other non lactose fermenting bacilli Though in
the maternity unit investigated both during and after the
outbreak paracolon bacilli were more frequent than in
the control series their distribution was not related to the
distribution of diarrhoea and vomiting

TRANSVESICAL SUPRAPUBIC PROSTATECTOMY WITH CLOSURE OF THE BLADDER

REVIEW OF 40 CASES

B E CRAWFORD STANLEY

M.B Lond, F.R.C.S

ASSISTANT, SURGICAL UNIT, ST MARY'S HOSPITAL, LONDON

The prostatectomies reviewed here were done by two
surgeons for benign enlargement of the prostate The
patients were consecutive admissions to the surgical
unit of a London teaching hospital and are unselected,
except that there was no blood urea level higher than
112 mg per 100 ml in the series The average age of
the patients was 69.8, the youngest 54, and the oldest 82

All the cases have been followed up for six to eighteen
months after operation

OPERATION AND POSTOPERATIVE MANAGEMENT

The operation used is a simple one Under general
anesthesia a suprapubic subumbilical incision is made
and the bladder opened at the fundus The prostate is
enucleated as for a Freyer's operation, and the cavity
immediately packed with gauze A retractor of the type
shown in fig 1 is inserted into the bladder With the
tip of the retractor depressing the bladder base, the
packed prostatic cavity is compressed against the sym-
physis pubis (fig 2) Pressure is maintained for three
or four minutes and, when the packing is removed,
it is found that the ooze of blood from the prostatic
cavity is considerably diminished Any tags of mucosa
round the internal urinary meatus are then trimmed, and

Fig 1—Retractor used in transvesical suprapubic prostatectomy
1/2 actual size

obvious and easily accessible bleeding points ligated with fine catgut or coagulated by diathermy. Much time is not spent on this manoeuvre. A 22 (F) McCarthy catheter is passed along the penis into the bladder. The catheter is depressed posteriorly with a retractor, and two or three plain catgut sutures are inserted to approximate the anterior part of the lateral borders of the internal urinary meatus. Each stitch takes a bite of about half an inch of tissue. These stitches do not pass as deeply as the anterior stitch described by Harris (1930, 1934). Sufficient are inserted to make the edges of the internal urinary meatus fit snugly round the catheter (figs 3 and 4). At the conclusion of the manoeuvre adequate haemostasis is obtained.

The catheter is then adjusted so that no eye lies in the prostatic cavity, and is fixed to the anterior wall with Esmay buttons. The bladder wall is sutured in two layers, a small drain is left in the cave of Retzius, and the peritones are closed.

After operation, tap-water is given per rectum by Murphy's method to combat shock. For irrigations through the catheter no hard and fast rule is laid down, it is left to the judgment of the nurses. Irrigations of one or two ounces of sterile saline solution are required hourly for the first few hours and subsequently at longer intervals. The catheter is left in situ for five to seven days, and the patient discharged soon after. These patients are not hurried out of hospital.

All the patients receive 250,000 units of penicillin twice a day and sulphadiazine from the time of operation until twenty-four hours after the catheter has been removed.

CONDITION TREATED

29 patients were admitted for a planned operation. 7 were admitted with acute retention, 4 of these were operated on immediately without passage of a catheter, and the other 3 treated with catheter drainage for from two to five days before operation. 4 patients had a suprapubic cystostomy some time before.

In addition to the prostatectomy, stones were removed from the bladder of 1 patient, three sacculi from the bladder wall of 1 other, and 2 other patients had papillomata of the bladder fulgurated.

RESULTS

1 patient died, on the fourth day after a cerebral thrombosis either during or immediately after operation. Postoperative complications are summarised as follows.

Clot Distension of Bladder—There was no condition demanding more than the use of a bladder in the ward.

Suprapubic Fistula—Suprapubic fistula developed 3 cases after the removal of the urethral catheter, healed in three, four, and eight days.

Secondary Haemorrhage—Slight secondary haemorrhage occurred in 3 cases. Of these 1 demanded no treatment, the other 2 were treated by replacement of the catheter three days.

Epididymo-orchitis—In this series vasotomy was done. In spite of the administration of penicillin and sulphonamides 16 patients developed epididymo-orchitis.

The results six to eighteen months after operation were:

General Health—30 patients reported feeling fitter than before the operation, 8 admitted to no noticeable change, and 1, who had post-prostatectomy obstruction, was not so well.

Micturition—8 patients reported that they did not rise at night to micturate, 9 rose not more than once, 20 rose not more than twice, and 2 rose three times. 35 patients reported that they passed a stream of urine as freely as they did when young, 3 said they micturated comfortably but not with great force, and 1 (post-prostatectomy obstruction) said that he micturated only with straining. 23 patients had less than one ounce residual urine, 14 between one and two ounces, and 2 than two ounces.

Urine—Of 16 patients with sterile urine before operation 15 had sterile urine at follow-up. The urine of the 1 gave a moderate growth of coliform bacilli, but the final result was very satisfactory. Of 23 patients who had infected urine before operation, 12 had sterile urine at follow-up. The remainder were still infected.

Late complications were seen in two cases. **Post-prostatectomy obstruction** followed an operation in which the anterior prostatic capsule had been torn through in the enucleation of a very adherent prostate. A hole about an inch in diameter with very ragged edges had to be repaired.

A slight meatal stricture occurred which required dilatation on three occasions after the patient had left hospital.

Fig 4—Completed suture of internal urinary meatus round catheter

Fig 3—Catheter in situ and of first stitch

DISCUSSION

This small series shows that a transvesical enucleation of the prostate, with insertion of two or three anterior haemostatic sutures and closure of the bladder, gives satisfactory results.

The only unsatisfactory feature is the occurrence of epididymo-orchitis, which shows that, in spite of antibiotics and

ly, vasotomy is still needed to prevent this cation extravagant claims are made for this operation is simpler technically than that of Millin (1947) and easily be performed without special instruments ilities It also has the advantage that it allows manoeuvres within the bladder—e.g., fulguration sillonata that are inaccessible to the cystoscope, removal of sacculi—to be done at the same time explanation of the success of this treatment he in the operation itself, because, in the history static surgery, operations involving closure of the er have been fraught with disaster, and it is only the advent of chemotherapy and antibiotics closed operations have been widely practised It these agents that its success must be attributed

SUMMARY

cases of closed transvesical suprapubic atectomy were done with satisfactory results e administration of penicillin and sulphonamides ot prevent epididymo orchitis in 16 of 39 patients suggests strongly that vasotomy should have done

y thanks are due to Prof C A Pannett director of the eal unit, St Mary's Hospital, for permission to include us series 21 cases on which he has operated It was at uggestion that this operation was given a trial

ACQUIRED IDIOSYNCRASY TO SODIUM *p*-AMINOSALICYLATE

JAMES CUTHBERT

M.D. Glasg., F.R.F.P.S., D.P.H.

DEPUTY MEDICAL SUPERINTENDENT, BAQUELEY SANATORIUM, MANCHESTER

HE toxic effects of sodium *p* aminosalicylate en for long periods in pulmonary tuberculosis are tunately rare Most workers agree that, apart from ld loss of appetite, nausea and vomiting, or occasional rrhœa there are few other dangers, but a few tances have been published of sensitisation developing h continued administration of the drug Rashes, h or without high pyrexia have been mentioned, and, ely, albuminuria or crystalluria The following case wed high pyrexia, an extensive rash followed by plete desquamation, enlarged tender superficial pph glands, albuminuria, temporary suppression of ae, and jaundice, which I have not seen previously orted

CASE RECORD

' married woman, aged 28, was admitted to the sanatorium Sept 12 1949 with pulmonary tuberculosis There was istory of allergy

' treatment—After a period of rest in bed an icial pneumothorax was induced on 26 but it was abandoned on Nov 22 Jan. 3, 1950, the erythrocyte sedimenta rate (E.S.R.), which had been 14 mm hour in the previous month, rose to am in 1 hour The patient was apyrexial he had been since admission, and her ght had increased by 11 lb A course of am P.A.S. 20 g in divided doses daily for days in each week, was begun on Jan 5 absence of nausea and vomiting was arkable

' progress—On Feb 4 the patient had a t rise of temperature (see figure) and symptoms of a cold in the head with ng limbs and back suffused face, and throat Since the pyrexia continued, was given intramuscular aqueous

penicillin 50,000 units t.d.s. She was ill, flushed, listless, and aching all over Chest radiography on Feb 10 showed no essential change

Feb 13 the patient had a rigor and projectile vomiting, and lumbar puncture produced clear cerebrospinal fluid not under pressure and containing 4 leucocytes per cmm and protein 20 mg per 100 ml A mild erythematous rash developed all over the face, neck, and extremities Penicillin was withheld but not the P.A.S. A blood count showed white cells 7900 per cmm (polymorphs 64%, lymphocytes 32%, monocytes 1% eosinophils 3%)

Feb 14 a Widal test was negative for the salmonella group and *Brucella abortus* Two consecutive blood cultures had been sterile The erythematous rash vanished and the patient felt better, her temperature falling to 98.4°F in the evening

Feb 15 jaundice appeared and steadily deepened Pyrexia returned P.A.S. was discontinued Calomel gr 2 was followed in six hours by mag sulphate gr 180 A fat-free diet and glucose in copious drinks were given In the forenoon a rash like sudamina developed on the arms and neck, this changed by the evening to an intense maculopapular rash

Feb 17 there was conspicuous jaundice, with an itching raised maculopapular rash all over the body, behind the ears, on the scalp and hard palate, and in the external auditory meati, where it caused a purulent discharge The rash was worse on the shins and absent from the palms, soles, elbows, and buttocks The glands on each side of the neck and in the axillæ and groins were enlarged and tender The white cell count was now 17,900 per cmm (polymorphs 40%, lymphocytes 40%, monocytes 2%, eosinophils 9%) 'Benadryl' 50 mg t.d.s. was given.

Feb 18 the rash more intense and the glands were still tender and palpable The patient had pains in the back and was acutely ill

Feb 20 Wassermann, Paul Bunnell, and Hess's tests were negative Thymol turbidity was 4.2 units per 100 ml The jaundice was less severe The patient's face was puffy and she still had pains in the back Examination with dark ground illumination of a fresh catheter specimen of urine showed no *Leptospira icterohæmorrhagæ*, and the inoculation of guinea-pigs was likewise negative Fouchet's test for bile pigment was positive The urine contained pus cells a few red cells, and hyaline and granular casts

Feb 22 albuminuria was present, and examination of the blood showed Hb 100%, and white cells 18,600 per cmm (polymorphs 48%, lymphocytes 24%, monocytes 11% eosinophils 17%) The pyrexia had been decreasing since the icterus had developed on Feb 15 Jaundice was not detected in the conjunctivæ now The temperature rose again in the evening to 100°F

Feb 23 pyrexia was still present and there was œdema of the legs and arms The rash was less extensive but becoming exfoliative The liver was palpable three inches below the subcostal margin Anuria suddenly supervened in the morning and no urine was obtained by catheterisation from 4 A.M. to 5 P.M. then incontinence of urine began and small quantities were passed The patient was extremely ill and not expected to survive Deep infra red irradiation was applied to the loins and lumbar region all day, and tinct scillæ 10 minims in water four times a day, was given until March 12

Feb 24 blood urea 18.63 mg per 100 ml

Feb 25 the temperature had fallen to normal, and the patient felt better

Feb 27 a blood count showed Hb 94%, red cells 4,730,000

Temperature chart during reaction to sodium P.A.S.

per c mm, and white cells 19,800 per c mm (polymorphs 24%, monocytes 10%, lymphocytes 61%, eosinophils 5%) The urine was acid and scalding on micturition Pot cit and sod bicarb were given regularly

Feb 27 and 28 the patient had diarrhoea, which was controlled by mustard and kino

March 1 the patient's evening temperature was 102.4°F, and her rash was desquamating all over her body (loss on the palms and soles) The underlying maculopapular rash had gone There were still pains in the loins, but the general condition had improved The patient had been continent of urine for three days The urine contained albumin, no bile salts, no sugar, no bile pigment, many pus cells, scanty red cells, and no casts, its reaction was neutral

March 2 the rash was profusely desquamating and the patient had low back pain but felt much better in spite of her pyrexia The white cell count was 21,400 per c mm (polymorphs 63%, lymphocytes 25%, monocytes 4%, eosinophils 8%)

March 5 none of the superficial lymph glands were now enlarged Desquamation was almost completed on head, trunk, and limbs, but was starting on palms and soles

March 6 a blood count showed Hb 74%, red cells 3,780,000 per c mm, white cells 15,000 per c mm (polymorphs 71%, lymphocytes 20%, monocytes 4%, eosinophils 5%)

March 7 pyrexia was still present, and the blood urea level was 20.35 mg per 100 ml

March 9 the skin had almost finished peeling, and the maculopapular rash was returning Benadryl was discontinued, and 'Anthusan,' two 0.1 g tablets t.d.s., was given There was no evening rise of temperature

March 13 there was no pyrexia, the patient felt drowsy but much improved, urine was being passed freely, and all oedema of face, arms, and legs had vanished The arms and abdomen were blotchy A patch test with sodium P.A.S. and a control was negative The dosage of anthusan was reduced to two 0.1 g tablets daily

March 17 anthusan was discontinued 'Nivea' cream was given, with benefit to the generally dry skin

March 20 there were slightly erythematous and itchy areas on the forearms and anterior aspects of the elbows A patch test with sodium P.A.S. on the front of the right thigh was now strongly positive after twelve hours' contact, the area covered by the patch being swollen and itching, with weeping of the skin. A control test without P.A.S. was negative, and similar P.A.S. tests on other patients not receiving P.A.S. therapy were negative

March 25 the evidence of the positive patch test was still visible as a scaly area The urine was free from pus cells and red cells, and had only a trace of albumin There were no loin pains or urinary symptoms Tests for sensitivity to penicillin and aspirin were negative

Desensitisation—On April 4 desensitisation was begun by the method used by Madigan et al (1950) After the first day slight itching erythema developed in the elbow flexures and round the site of the positive patch test, but this soon subsided, and the dosage of sodium P.A.S. was continued The white cell count was 13,700 per c mm (polymorphs 59%, lymphocytes 24%, monocytes 7%, eosinophils 10%) The urine now contained no albumin, red cells, or casts

DISCUSSION

Unfortunately we did not watch the blood P.A.S. levels By the time the rash and jaundice had developed and we suspected an idiosyncrasy to P.A.S., the veins, poor at any time, could not be induced to yield sufficient blood for estimation However, idiosyncrasy to P.A.S. can be acquired without a high blood P.A.S. level (Hemming and Stewart 1949) It is noteworthy that during the thirty days of P.A.S. therapy before the onset of pyrexia the patient had no upset of appetite, diarrhoea, nausea, vomiting, or any other toxic disturbance We have gained an impression from a study of blood P.A.S. levels in other cases that vomiting and diarrhoea tend to keep those levels low, whereas they rise in the absence of vomiting and diarrhoea

At the outset of this illness penicillin was given for eight days The same penicillin caused no ill effects in any other patients in the hospital, and later the present case showed no evidence of penicillin sensitivity

Erdei and Snell (1948) saw no toxic reactions in cases of pulmonary tuberculosis treated with P.A.S. they think that such reactions described mark impurities remaining in commercial P.A.S. not to the P.A.S. itself.

The sodium P.A.S. used in the present case stock solution and caused no upset apart from nausea, vomiting, and diarrhoea in any of the other cases That a patch test done with sodium P.A.S. was so strongly positive in the present case in control patients shows that this was a true sensitivity Published reports of severe toxic effects to P.A.S. therapy are scanty

Madigan et al (1950) studied 64 cases who had been on sodium P.A.S. daily with pot cit as required to keep urine alkaline, 32 patients had nausea and 22 had diarrhoea, and vomiting Three cases of severe toxicity to P.A.S. were reported two of them showed generalised itching skin rash followed by desquamation Patch tests in this case, unlike ours, were positive for aspirin but not for P.A.S. The same workers, in a study of the side effects of P.A.S., say that about half the patients develop some intolerance to fatty foods

Kierland and Carr (1949) reported two cases of severe fever and pruritic erythematous eruptions due to P.A.S. the reactions being so severe that the drug had to be discontinued They had seen two other patients with severe skin reactions but without fever

Horne (1949) describes a case with pyrexia, oedema of face and conjunctivae, intractable cough, and an intractable erythematous blotchy rash Small doses of P.A.S. elicited the same effects, but a patch test was negative to P.A.S., and there was no eosinophilia. The present case showed none of the intractable coughing described by Horne or by Hemming and Stewart (1949) in one of their cases Horne effected a remission successfully by increasing the doses of sodium P.A.S. from 0.1 g five times a day to 15 g daily

Hemming and Stewart (1949) report a case with generalised skin irritation but no rash This patient was extremely ill with fever, photophobia, nausea, headache, and restlessness It was thought to be a true case of acquired idiosyncrasy Their second patient had a severe urticarial rash, but under treatment with sodium P.A.S. 10 g daily, excreted, after four weeks, an increased amount of urinary protein, with a few red cells and numerous hyaline and granular casts in the urine, and had occasional transient oedema After withdrawal of the P.A.S. excretion of urinary protein slowly decreased and became stabilised at 10–12 g daily In some 40 patients treated with P.A.S. the urine occasionally contained red cells, but it was not necessary to discontinue P.A.S. treatment Hemming and Stewart think it probable that the glomeruli were affected in some way by increased filtration of protein

Nagley and Logg (1949), analysing 37 cases treated with P.A.S., state that in their experience P.A.S. is remarkably free from toxic effects and can be continued without interruption for many months without untoward results Four of their cases developed haematuria and albuminuria, with a deposit of uric acid crystals in the urine They cleared on treatment with alkalis and withdrawal of P.A.S. for a few days, and further effects when treatment was started again

The present case exhibits some unusual features Pyrexia and a maculopapular rash followed by desquamation were outstanding Anuria (which has not been mentioned previously) lasted thirteen days It is impossible to say whether this was due to action or to blockage by swollen renal epithelium Jaundice in such circumstances does not seem to have been described before, nor has the presence of enlarged lymph glands in the neck, groins, and axillae

aphased previously. There was no infective in the hospital or immediate neighbourhood at the time. The jaundice could have been obstructive, giving a general thickening of skin and mucosae in the reaction. On the other hand, both the jaundice and renal damage could have been a toxic side effect of the drugs. We have insufficient evidence to be certain. The patient was extremely ill and on the point of death. Knowing what I now do, I would stop the therapy and substitute anti-histamine drugs on the basis of pyrexia in the absence of intrapulmonary or demonstrable cause, or on the first sign of a rash. Treatment of scarlet fever. Desensitisation can be done earlier, and I think it should be done because of the easing use of drugs with a salicylic acid derivation might possibly precipitate a return of the alarming manifestations at a later date.

Thanks are due to Dr H. G. Trayer, medical superintendent, Guy's Sanatorium, for permission to publish.

MEIGS'S SYNDROME

D BERESFORD R AIDIN
 J Wales, M.R.C.P. M.D. Dubl., D.C.P.
 MEDICAL REGISTRAR MORBID ANATOMIST
 SOUTHMEAD HOSPITAL, BRISTOL

Long ago as 1879 Cullingworth recorded a case in which fibroma of the ovary was associated with ascites and hydrothorax, and another was described by Tait in 1902. But a definite clinical syndrome was not described until 1937 when Meigs and Cass reported ascites (four of their own and three others) and hydrothorax have also been observed with a tumour other than fibroma of the ovary. Thus MacFee reported a case of cystadenoma of the ovary which had a similar clinical picture, and Schenck and Eisner and Anderson (1944) reported cases in which malignant tumours of the ovary were responsible. Meigs (1943) suggested that when these cases formed a definite enough group they should be included in the syndrome which bears his name.

The following case is an example of papillary adenocarcinoma of the ovary producing ascites and hydrothorax in the absence of secondary deposits in the peritoneum or pleura.

A married woman, aged 77, was admitted to hospital on April 1, 1948, with three or four months' history of gradually increasing abdominal distension. On examination she was obese and had not apparently gained much weight. There was moderate oedema of both lower limbs, but the neck veins were not distended, and she could lie flat in bed with very little distress. The heart did not appear enlarged, the heart sounds were normal, no murmurs were heard. The blood pressure was 100/60 mm Hg. There was a moderately large pleural effusion on the right side. The abdomen was grossly distended and apparently contained free fluid. No mass was palpable in the abdomen, the spleen and liver did not seem to be enlarged.

Investigations.—Paracentesis abdominis was done soon after admission, 5 litres of yellowish fluid being removed. The fluid contained occasional cells that could not be identified. Paracentesis was repeated four times, the total amount obtained varied from 2 to 4 litres and no cells were seen in the deposit. No mass or enlarged viscera were discovered at paracentesis. The chest was aspirated soon after admission, a straw-coloured fluid free from cells being removed.

Investigations.—The blood proteins were estimated on two occasions. On Dec 17, 1948, the serum albumin was 4.16 g,

and the serum globulin 2.80 g, per 100 ml, and on Feb 3, 1949, the serum albumin was 3.21 g and the serum globulin 3.11 g. A Wassermann reaction was negative, and the urine contained only a trace of protein.

Progress.—The patient's general condition being fairly satisfactory, she was discharged on Feb 12, 1949, and readmitted at intervals for paracentesis abdominis.

Readmission.—She was readmitted on April 10, 1949, much worse. She was cyanosed and extremely dyspnoeic, and had large bilateral pleural effusions in addition to her ascites. In spite of aspirations of the fluid her condition deteriorated and she died two days after admission.

Necropsy twenty-four hours after death showed that the peritoneal cavity contained 2-3 litres of serous fluid, and both pleural cavities a large quantity of amber fluid, the pericardial fluid was also in excess of normal. The pericardium appeared normal. The heart weighed 270 g and showed no abnormality. Both lungs were greyish black and almost completely collapsed. No secondary deposits were found in the lungs or pleurae. The liver weighed 1170 g and appeared normal. The uterus was bulky and had a small submucous fibromyoma growing from the fundus. The right ovary was normal, but the left was replaced by a cystic tumour measuring 60 x 40 x 40 mm. It was covered by a smooth whitish membrane through which dilated venules were seen. Attached to the main tumour was a smaller mass measuring 20 x 10 mm. The pelvic colon was firmly adherent to the tumour, which was loculated and contained serous fluid and an irregular dark red friable growth. Microscopy showed the growth to be a papillary adenocarcinoma degenerating in places. Microscopy of the lung, pleura and peritoneum gave no evidence of secondary deposits.

DISCUSSION

This case is reported as an example of Meigs's syndrome associated with a malignant neoplasm of the ovary. Though it is generally known that the syndrome occurs with simple tumours of the ovary, its association with malignant tumours is less well known. It is important to recognise the syndrome, because removal of the tumour is followed by disappearance of the effusions (Meigs and Cass 1937). As in the present case, because of their presenting symptoms these patients are often admitted to a medical ward with a diagnosis of congestive heart-failure or of cirrhosis of the liver, both of which can be associated with ascites and hydrothorax. If the diagnosis is in doubt, peritoneoscopy should be performed, and, if necessary, exploratory laparotomy.

The cause of the effusions is not known, and various theories have been brought forward to explain them.

Selye's (1936) alarm reaction has been suggested as the mechanism responsible. This hypothesis suggests that the effusions are the result of an irritant which produces a hypersensitive state (in this case a pelvic

Ovarian tumour showing adenocarcinoma. (x 400)

ing the case with which meningitis leptospira confused with other forms of lymphocytic is unless serological examinations are undertaken in this country the meningitic syndrome to be more often attributable to *L. canicola*, in ant case *L. icterohæmorrhagiae* was responsible rains of leptospira have been found pathogenic Continent It is not unknown for cases of is leptospira to be complicated by ocular nystagmus, optic neuritis, transverse myelitis, pheral neuritis (Scheid 1949) The possibility ision with syndromes caused by neurotropic ill therefore be appreciated

r be argued that the incidence of leptospirosis country is not great enough for serious con n , but, since the seasonal incidence is the same of poliomyelitis (July to November), and upwards of dogs in different towns are infected (Broom Intvre 1948), some cases of so called lymphocytic is and poliomyelitis may possibly be leptospirosis

sh to thank Dr J C Broom, of the Wellcome ries of Tropical Medicine for his help in making ological tests, and Dr E W Hart for permission to he case

Preliminary Communication

RELIEF OF POSTOPERATIVE PAIN AND INTESTINAL MOTILITY

fact that morphine has a constipating action is own, and this important side effect has to be ed when the drug is used for the relief of post e pain It would therefore be useful to have gesic which would not interfere with normal al function, particularly after operations predis o distension or other undesirable gastrointestinal ations We present here the results of a quanti omparison of the effects of morphine, pethidine, idone ('Physeptone') upon the propulsive power ntestine in conscious dogs

operation has already been described (Streeten ughan Williams 1950) by means of which cannulæ rted into both ends of a "Thury Vella" type of al loop A segment of gut, 4-6 inches in

- A) Resection of loop
 B) Anastomosis and annulation of loop.
 C) Completed preparation

nd reach it via a pedicle of mesentery which is act Plastic cannulæ are then sewn into both the loop, and are brought out through separate ab incisions in the abdominal wall The end result g which leads a normal life, but from whose n protrude two cannulæ, one of which lies in en of the proximal, the other of the distal, end gment of intestine, which retains its normal pply

Fig 2—Ordinate total reduction of propulsive work caused by the drug Abcissa dose of drug, in mg per kg body weight on a logarithmic scale

Before experiments the dog lies quietly on its side, and watertight joints can be made between the cannulæ and recording apparatus Tyrode solution is then allowed to run at normal dog temperature into the upper end of the loop, which pumps it round and expels it from the lower end By means of three separate recorders tracings are made, on a smoked drum, of the contractions of the proximal end of the loop, of the contractions of the distal end, and of the rate at which fluid is expelled from the loop The movements of intestinal loops of this kind are usually recorded by means of balloons or boluses inserted into the lumen Neither can be said to be normal constituents of the bowel contents, and the present method, which employs Tyrode solution, represents an endeavour to imitate the physiological conditions normally existing in the small intestine, whose contents are, of course, fluid It is a development of a method recently described by Gregory (1950)

The pressure of the fluid entering the loop can be controlled, as can the height to which this fluid must be propelled before it can flow into the outflow recorder Thus the loop can be made to work under any conditions of pressure, and it has been our practice to keep the inflow pressure at a lower level than that of the outflow The amount of propulsive work done by the loop can thus be precisely estimated For example, if, in the course of five minutes, the loop raises 5 ml. of Tyrode, entering at a pressure of 6 cm water, to a height of 8 cm water, it has performed 10 g cm work—i.e., is working at a rate of 2 g cm propulsive work per minute

Morphine, pethidine, and amidone all reduce the rate at which propulsive work is performed by these loops Two methods have been adopted for estimating their comparative potencies The first has been to determine the smallest dose of each drug which will just cause a significant reduction in the work done The second has been to plot, against the logarithm of the dose injected, the difference between the amount of work done after injection and that which would have been expected but for the action of the drug When a steady rate of work was established, the injection was made, and the total reduction of propulsive work before the original rate was re-established was then calculated from the tracings In fig 2 the reduction of work is plotted against the logarithms of the doses of the three drugs

Morphine is the most powerful inhibitor of propulsive work, and the following figures give the relative potencies of the three analgesic drugs, as calculated by the two methods described above, in terms of the number

tumour), but it does not explain why only some pelvic tumours produce the syndrome

Pressure of the abdominal lymph channels by the pelvic tumour has been suggested by Schenck and Els (1939) as the cause of the ascites. The hydrothorax is explained by anaphylaxis and obstruction to the flow of lymph. This hypothesis postulates a large tumour as the cause of the lymphatic obstruction, but not all the tumours are large, and, as in the case we report, some are quite small.

Alteration in the blood protein levels is unlikely to cause the effusions, because a different clinical picture would be produced. In the present case the blood-protein levels were normal on two occasions, and normal levels have been found by other observers.

Dockerty and Masson (1944) observed that oedema of the tumour and/or the pedicle appeared to be related to the ascites, which was absent when there was no oedema. They also pointed out that adhesions were present in 30% of cases with ascites, and suggest that the degeneration of the tumour produced the ascites. Obstruction to the venous return by twisting of a pedicle may also be a factor in the production of ascites.

The explanation of the hydrothorax is much more difficult. Though Meigs et al (1943) demonstrated the passage of particulate matter through the diaphragm (probably through diaphragmatic lymph channels), they do not explain why all cases of ascites do not develop hydrothorax. However, Marshall (1949) finds that all cases of ascites have some pleural effusion, and suggests that this can be adequately explained by passage through the diaphragmatic lymph channels. He thinks that the size of the hydrothorax depends on the size and rate of formation of the ascites and the individual characteristics of the patient.

Not all pathologists agree that some effusion accompanies all cases of ascites, and no attempt is made to explain why the hydrothorax is often unilateral. Further, massive hydrothorax does not occur with ascites apart from this syndrome and some cases of cirrhosis of the liver, unless there is some obvious cause, such as heart-failure, nephritis, or carcinomatosis. In these conditions there is very good reason for the hydrothorax, but further investigation is required to solve the problem in Meigs's syndrome.

SUMMARY

A case of Meigs's syndrome associated with a papillary adenocarcinoma of the ovary is reported.

The literature is briefly reviewed and various theories of the causation of the effusions are outlined.

We wish to thank Dr P. Phillips for permission to publish this case, and Mr G. H. Rogers for the photograph.

" If a new drug or combination of drugs, safe and highly effective in the treatment of tuberculosis, should be discovered in the year 1950, one might be tempted to assume that eradication would take place quickly and automatically. In reality the responsibilities of those charged with tuberculosis control activities would be immediately increased. There would be a moral obligation enforced by a vocal public opinion, to see that every case, in any stage of the disease, received the new therapy. The immediate demand for hospital beds might be so tremendous as to constitute an emergency. —Dr FLOYD M. FELDMANN, *Amer. Rev. Tuberc.* June, 1950, p. 892.

MEDICAL REGISTRAR

LATE HOUSE PHYSICIAN

HAMPSTEAD GENERAL HOSPITAL, LONDON

In recording a further case of meningitis in the London area, our purpose is to draw to the ease with which this disease may be confused with the meningitic stage of poliomyelitis during epidemic.

CASE RECORD

On Aug. 14, 1949, a boy, aged 7, walked into the department of this hospital with a history of a day or a few hours' intermittent abdominal pain, and He had vomited three times in the morning but had not been put to bed.

On examination he was quiet and flushed but could not talk without distress. His temperature was 101°F, pulse rate 110, and his respirations were 22 per min. There was no conjunctival suffusion, the fauces were normal, and the posterior cervical glands were palpable, but the glands were not enlarged. There was slight neck stiffness but the boy could kiss his knees easily, and there were no other abnormal neurological signs. The ears and fundi were normal. He was admitted to a side ward as a case of poliomyelitis in the preparalytic stage.

Investigation.—On the morning after admission a lumbar puncture produced clear colourless cerebrospinal fluid (c.s.f.) under normal pressure containing less than 1 cell per mm. with protein 20 mg. and chloride 0.18 mg. per 100 ml. Sugar reduction was normal. A blood-count showed a leucocytosis of 10,000 cells per c.mm. (polymorphs 45% with a shift to the left).

Progress.—For the next four days the patient had fever (maximum temperature 103.5°F). On Aug. 17 severe conjunctival suffusion of the eyes was noticed and there was considerable neck stiffness. On Aug. 18 there was a positive Kernig sign but no muscular weakness or tenderness and no change in the tendon reflexes. The fundi were normal and there was no conjunctival discharge. Lumbar puncture produced cloudy c.s.f. containing 880 cells per ml. (polymorphs 15%, lymphocytes 80%, mononuclears 5%), protein 55 mg. per 100 ml. with a slight excess of globulin, and normal amount of sugar and chloride. No organisms were seen in the smear or on culture. A blood-count showed 6000 white cells per c.mm., with a normal differential count. Blood-culture and urine examination showed no abnormality.

Diagnosis.—In view of the conjunctival suffusion and the late development of a leucocytosis in the c.s.f., the possibility of leptospirosis was considered. It had been noted that the boy spent weekends at a camp on a backwater of the Thames at Staines, and bathed frequently in the river, he admitted that there were numerous rats around the bathing area.

Treatment and Progress.—A course of intramuscular penicillin 250,000 units t.d.s. was started on Aug. 18, and from then on the patient remained afebrile, and clinical recovery was complete in three days. He was discharged on Sept. 1 and was seen again a month later, when he was admitted with a dislocation of the right elbow, at that time he was otherwise completely well.

Agglutination reactions against leptospira were tested at the Wellcome Laboratories of Tropical Medicine, with the following results:

- Aug. 19.—Agglutinations negative at all dilutions against *Leptospira icterohaemorrhagiae* and *L. canicola*.
 Aug. 24.—Agglutinations positive at 1/300 with *L. icterohaemorrhagiae* and at 1/10 with *L. canicola*.
 Aug. 30.—Agglutinations positive at 1/300 trace at 1/1000 with *L. icterohaemorrhagiae* and positive at 1/30 with *L. canicola*.

Agglutination tests made on the blood of the boy's mother and brother, who camped with him, were negative.

DISCUSSION

Leptospirosis has been recognised, and outbreaks of the various forms have been described, for over a hundred years, the epidemiology and clinical features have been reviewed by Walch Sordrager (1939). In recent years several small series of cases have been published in this country (Robertson 1946, Buzzard and Wylie 1947).

THE LANCET

LONDON SATURDAY, AUGUST 5, 1950

Ætiology of Infantile Enteritis

the past decade more than 3000 infants under year have died annually from gastro enteritis in land and Wales, giving mortality rates of 4-5 per 1000 live births. It is true that there were ten times as many deaths from this disease fifty years ago, and the high seasonal wave gave it the name summer diarrhoea. It is also true that the seasonal wave has been flattened and the disease now occurs, in an apparently sporadic form, through summer and winter. All the same, with an infant-mortality rate now down to about 30, it seems hardly to the credit of public health measures that 4 or 5 of every 1000 infant deaths are from an infection that is probably preventable. Preventive measures, if not entirely dependent on, are certainly helped by a knowledge of the causative agent of a disease, and part of the problem with infantile enteritis is that its ætiology is still obscure. It is, in fact, a syndrome of varied ætiology, ranging from mild dietetic upsets through enteritis associated with parenteral infections to many cases of gastro enteritis of undoubted infective origin. In this last group, clinical and epidemiological evidence suggests that there is more than one causative agent. Besides the cases associated with accepted intestinal pathogens of the salmonella and shigella families, there have been outbreaks in maternity units affecting both infant and mother, and other outbreaks, usually mild, affecting breast fed and bottle fed infants impartially. And there have been extremely severe outbreaks in which the brunt of the attack has fallen on the artificially fed or premature infant. Such outbreaks have been more common in America than in this country and have encouraged the view that "epidemic diarrhoea of the newborn" is a disease sui generis, though in its clinical picture it closely resembles the diarrhoea and vomiting of older infants. Inquiries into the ætiology of gastro enteritis have largely been concentrated on institutional or community outbreaks of this severe form in newborn infants, and the recent investigations in Britain implicating a specific serological type of *Escherichia coli* as a possible causative agent have been corroborated in the U.S.A. and in Scandinavia. This *E. coli*, whose taxonomy may not be decided until a satisfactory serological classification of the coliform group is adopted, masquerades under a variety of names—*Bact. neopolitana*, α type, D 433, B.G.T., &c—and it has already been joined by another claimant to pathogenicity, called the β type¹. The present situation is analogous to that when the serology and pathogenicity of the pneumococcus family began to be unravelled. Indeed, infantile enteritis has epidemiological similarities with infantile pneumonia, in which the infecting pneumococcus is often an endogenous strain like types 6, 19, and 23, but sometimes an epidemic exogenous strain like types 1 and 14.

Meanwhile, more data on the relation between *Bact. coli* D 433 and diarrhoea are being collected. The opening paper in this issue reports the details of two outbreaks of neonatal diarrhoea in a Liverpool maternity unit, one of great severity associated with *Bact. coli* D 433 and mainly affecting artificially fed infants, the other a mild infection occurring equally in breast-fed and bottle fed babies. The first outbreak was concentrated in the premature unit (separate from the main block), where within three weeks 10 of the 12 babies at risk developed diarrhoea and half of them died. *Bact. coli* D 433 was profusely present in the stools of the 10 ill babies and was not found in the 2 infants who escaped. In addition, there were 7 cases among 28 babies who were nursed continuously in the nursery, and *Bact. coli* D 433 was isolated from all 7 cases. There were no cases in the main wards where infants were nursed beside their mothers but taken to the nursery for bathing and changing. Of 12 infants discharged with positive swabs, 7 became ill within nine days, and all but 1 (who died at home) were again positive when re-swabbed. On the other hand, 62 out of 112 infants who were discharged with negative swabs were followed for at least a fortnight and all remained well, though 2 out of 25 who were re-swabbed were carrying *Bact. coli* D 433. Of the other 50 infants, 4 who became ill gave positive findings on readmission to hospital. When 55 healthy infants in the main block were swabbed five weeks after the last case of diarrhoea, there were no positive swabs but 9 out of 25 babies repeatedly examined in the premature unit gave positive swabs without developing any diarrhoea. The occurrence of symptomless carriers during or after an outbreak calls for little comment, since similar findings are common in outbreaks of salmonella and shigella infections. What is more unusual is the demonstration of the suspected pathogen in large numbers in the stools three days before the onset of symptoms. This finding, together with incubation periods of nine days or more, seems to invalidate the view that *Bact. coli* D 433 is the primary or only pathogen, to this should be added the general malaise preceding the diarrhoea or vomiting, and the absence of inflammatory changes in the bowel, which suggests a systemic infection. However, there has been no evidence of a *Bact. coli* septicæmia such as occurs in the somewhat analogous condition of calf scours. Is it possible that in this epidemic enteritis there is a symbiotic virus and bacterial ætiology of the kind that causes swine influenza? The arguments for a virus ætiology have been reiterated by LIGHT and HODES,² who have produced enteritis in calves by introducing a filterable agent derived from newborn infants suffering from a mild diarrhoea that affected both breast fed and bottle fed babies.

Experimental proof of the pathogenicity of the *Bact. coli* strains is hard to come by, though Dr KIRBY and his colleagues in Liverpool had some success with experiments on adult volunteers. The occurrence of *Bact. coli* D 433 in the stools of adult patients with diarrhoea has been reported by STEVENSON³, while, on the other side, PAYNE and COOK⁴ found the same organism in the faeces of 17 out of 60 healthy institutional babies who were being

² Light J S Hodes H L *J exp Med* 1949 90 113

³ Stevenson J S *Brit med J* July 22 1950 p 195

⁴ Payne A M M Cook G T *Ibid* p 192

of molecules of active base required to produce the same effect as one molecule of morphine base

	Morphine	Amidone	Pethidine
Threshold dose	1	2.86	784
Dose required to reduce work done by 100 g. cm	1	2.54	750

Translating these figures into their equivalent doses for a human subject of 70 kg, it appears that, whereas morphine (gr $\frac{1}{4}$, 15 mg) would abolish propulsion of fluid for an hour or more, the same dose of amidone would be only just sufficient to cause a detectable inhibition, and pethidine in doses as high as 200 mg would be well below the threshold for inhibition of propulsive activity.

It is emphasised that the method described here measures the *propulsive* power of the intestine. Morphine, as is well known, can give rise to a contracture of intestinal muscle. The advantage of the present method is that it distinguishes between such contractures and effective propulsive contractions. Indeed, it demonstrates that the contractures are not only ineffective for the propulsion of intestinal contents, but are actually inhibitory.

The assay demonstrates also that if a sedative is required which does not inhibit intestinal propulsion,

pethidine is much less inhibitory than morphine or amidone. Other work, both by ourselves and others, has shown considerable similarity in the reactions of human and canine gut, and these are presented in the hope that they may provide additional evidence on which a choice of sedatives (of paralytic ileus, for example) may be based.

SUMMARY

1 A quantitative comparison has been made of the effects of morphine, pethidine, and amidone on the propulsive power of the intestine in conscious dogs.

2 It has been found that whereas morphine and amidone, in doses equivalent to those used in man, have a marked inhibitory effect, pethidine, even much larger doses, does not interfere with propulsion.

Reviews of Books

Cancer of the Breast

Clinical Study of 1042 Cases Treated at Radiumhemmet, 1936-41 BENGT A. NOHRMAN Stockholm Esselte Aktiebolag 1949 Pp 98 Sw. Crowns 15

THIS study contains much information of great interest to all concerned with the treatment of cancer of the breast. The material consists of 1042 cases examined in the Radiumhemmet, Stockholm, from 1936 to 1941 inclusive, all of which were followed up for at least five years, 57 cases were treated at other hospitals and 118 were first seen with recurrence or metastases, while 45 were beyond treatment at the time of first examination. A special analysis is made of cases referred from the Karolinska and Sabbatsbergs Hospitals because nearly every patient operated on for carcinoma of the breast was sent to the Radiumhemmet for radiotherapy. This material is examined from many points of view, and all the usual factors are brought out—age incidence, marital state, pregnancy and lactation, heredity, and symptomatology. Classification is discussed in detail, the cases being grouped as operable and inoperable according to definite criteria (the most important being fixation of tumour and axillary metastases to the wall of the thorax). A statistical formula is used to allow for deaths from causes other than cancer of the breast, and after various factors, such as duration of symptoms, age, menopause, pregnancy, and lactation, in relation to prognosis, have been discussed, the results of different methods of treatment are compared. The absolute survival-rate on the whole material was 40.1%, on the operable cases 49.5%. These figures are further broken down to give detailed effects of preoperative and post-operative irradiation as carried out in a famous centre.

Quinidine in Disorders of the Heart

HARRY GOLD, M.D., professor of clinical pharmacology, Cornell University Medical College New York Paul B. Hoeber 1950 Pp 115 \$2

QUINIDINE is a drug with a limited application, though highly effective in its proper sphere. Its applications have not perhaps been studied as carefully as they might by all who employ it. Professor Gold briefly explains how to avoid its misuse, and what are the appropriate conditions and effective dosage in which to give it. He discusses the pharmacology, dosage, and toxic effects, and then the treatment of the main disorders of rhythm for which quinidine is helpful. The book is simply written and practical, and should be consulted by anyone not fully experienced in the use of this drug.

Helpful Hints to the Diabetic

W. S. COLLENS, B.S., M.D., chief of the diabetic clinic, Maimonides Hospital, New York, L. C. BOYD, M.D., chief of the diabetic clinic, Greenpoint, New York Springfield, Ill. Charles C. Thomas Oxford Blackwell Scientific Publications 1949 Pp 121s 6d

THIS book, by the authors of *Modern Treatment of Diabetes Mellitus*, is written for the patient to put him with all the practical information he will need to manage his diabetes successfully. Various other books have had the same object, and their very different show how difficult it is to attain. This latest work is highly readable and has profuse illustrations, both in colour and monochrome, which bring out well the technique of injection and urine-testing. The text contains one or two assertions which would be to substantiate. For instance a single lump of is unlikely to overcome an early hypoglycemic especially where this is due to protamine zinc and few patients indeed can attain the authors' aim of not allowing their blood sugar to exceed 120 mg/100 ml.

For British readers the book has a number of limitations inherent in the differences in standardisation and practice which hold between this country and the U.S.A. Thus the colour pictures of U.S. insulin preparations would serve only to muddle the British patient, and the omission of caloric values in the description of diets would be directly misleading. Then there are words such as podiatrist (ohropodist?) and a number of specific foodstuffs which are outside our experience. The rationale of dieting and the plea for standardisation of syringes are well and opportunely expressed, but the description of the Busher automatic injector, which passes the needle through the skin at an angle of 45° on a retractile trigger, seems only to complicate a normally simple procedure. Time schedules for various sorts of insulin injections and appropriate distribution of meals are expressed on a number of circular figures, but the first three refer to a single daily dose of unmodified insulin and have no application to modern diabetic treatment. There is a ring chapter on diabetic quackery, which, if less pertinent in this country, certainly drives home the truth of the position held by parenteral insulin in the treatment of diabetes. The book ends with a quiz and answer section which reviews the main practical points in the text.

While the book is not well suited to British patients for whom it was not in fact designed, it does contain much sensible information. It is a pity that the approach is so negativistic. The diabetic is told in no terms what he must not do and why, but there is too much stress on the many things which he can still do and should be encouraged to do.

d the tone and motility of the colon (contrary to the results of other observers), he therefore deduced that morphine would favour the production of operative distension. INGELFINGER¹¹ opposed the use of morphine in this condition because it hinders the transport of gas or chyme. This conflict is difficult to resolve, mainly because there are no reliable records of the action of morphine in these unusual circumstances. It might be feasible to use the technique that ALSTEAD and PATTERSON¹² used in their assessment of intestinal cramp-relieving agents in a study of the effects of morphine and other spasmolytics on intestinal propulsion (as judged by the degree of flatus) after abdominal operations. Finally, there is the possibility that intestinal distension may be affected by the central nervous actions of these spasmolytics. In dogs morphine causes an initial increase in intestinal propulsion through central vagal stimulation, but there is no good evidence for such an action in man.⁴ However, where much pain and discomfort are associated with distension, the drug's central analgesic and sedative actions may indirectly damp down the activity of the overstimulated sympathetic centres, since sympathetic stimulation diminishes the propulsive activity of the bowel, this depressant effect of the controlling centres may facilitate the passage of flatus. This may perhaps explain why some observers have claimed that morphine is beneficial in patients with intestinal distension.

Annotations

THE NATIONAL COLLECTION OF BACTERIA

At the beginning of this year the National Collection of Type Cultures transferred those of its bacteria which were not primarily of medical or veterinary interest to the Department of Scientific and Industrial Research and the Agricultural Research Council. This is in line with the policy of decentralisation among specialist institutions which was adopted by the Medical Research Council in 1944, when the collection, with its 5000 cultures, had expanded beyond the capacity of its original staff.¹³ Since then the fungi and protozoa have been divided between the London School of Hygiene, the Commonwealth Mycological Institute at Farnham, and the Institute of Brewing, and for two years the bacteria have been included. Any regrets that the public may feel at the passing of the bacterial museum where research workers, university teachers, commercial bacteriologists, and the merely curious could all on getting anything from *Acetobacter aceti* to *Staphylococcus aureus* will be tempered by the thought that the quality has made way for quantity. In the new laboratories at Colindale, where the collection has now been housed for a year, the cultures are being re-examined, their identities checked, and with the new drying-plant it will be possible to supply teachers at home and abroad with the usual organisms in the form of an elegant "succinate". Despite their unattractive name these dried cultures have many advantages over the familiar agar slants, and the drying process should much reduce the chances of contamination and antigenic changes through repeated laboratory manipulations.

In the collection's new *List*,¹⁴ organisms are grouped into three orders, as follows:

Order	Family	Genus
Actinomycetales	Actinomycetaceae	Actinomycetes Nocardia Streptomyces
	Streptomycetaceae	
Bacteriales	Mycobacteriaceae	Mycobacterium Corynebacterium Erysipelothrix Fusiformis Bacillus
	Bacillaceae	Clostridium Lactobacillus Streptococcus Leuconostoc
	Lactobacillaceae	Staphylococcus Micrococcus
	Coccaceae	Bacterium Chromobacterium Kurtzia Proteus Salmonella Shigella
	Enterobacteriaceae	Pseudomonas Spirillum Vibrio
	Pseudomonadaceae	Actinobacillus Brucella
	Parvobacteriaceae	Haemophilus Pasteurella Pfeifferella
Spirochaetales		Leptospira

The nomenclature follows the 3rd edition of "Topley and Wilson" rather than the new Bergey's *Manual*, but those of us who are still following the classification of the first edition of the *List* may be surprised to find that the genus *Staphylococcus* now includes all catalase positive gram positive cocci, many of which were previously listed under *Micrococcus* or *Sarcina*, *Staph. pyogenes* (*aureus*) is said to be the only clearly defined species, all the others being divided for convenience into five groups, A-E. In the genus *Pseudomonas* only about a sixth of the species survive, but the table of salmonellas becomes increasingly like a page from a gazetteer.

The new *List* is more than a catalogue of reliable goods with its background of patient continuing toil it will be an indispensable guide for medical workers of many kinds in many lands.

SAFETY IN MINES

THE latest report on research on safety in mines¹⁵ contains much information of interest to medical men, and especially to those whose work brings them into contact with mining communities. The investigations described have a very wide range, including, for example, coal-dust explosions and the use of mining explosives, the detection of mines gases, safety of haulage and winding gear, the investigation of dust, and the testing of mining equipment.

Dust Explosions—The use of stone dust to dilute the coal dust and so prevent explosions is at present indispensable. Damping the dust is a further precaution. It has been found that complete protection can be achieved only by the use of wetting agents (e.g., 'Teepol'). This reduces the inflammability of the stone dust, whereas water often binds stone dust and leaves the adjacent coal dust dry and unprotected.

Mines Gases—The coalminer is constantly exposed to the risk of gassing, and the recent standards of ventilation control laid down in 1947 have emphasised the need for reliable methods of determining the presence and concentration of different gases. Accurate methanometers are now available and can be used without further expenditure of man power, but attempts are still being made to find a suitable instrument for the estimation of small quantities of carbon monoxide. It has been found that synthetic rubber bladders used for the pre-analysis collection of mines gas are preferable to those made from natural rubber for the loss of gas by diffusion is less.

The use of diesel engines for underground haulage has increased the risk of gassing from carbon monoxide and nitric acid (NO₂) which are present in the exhaust gases.

regularly examined, in 6 of them the *Bact coli* was present in large numbers for three weeks or more, and at one time as many as 10 out of 15 infants were excretors without there being any intestinal symptoms. Thus, the picture is still confused. More work is needed on the antigenic analysis of the coliform group and the possible pathogenicity of particular members, as was suggested by the studies of KAUFFMANN and VAHLNE. If certain types are found to have epidemic propensities, more knowledge of their modes of spread should lead to better preventive measures. Meanwhile, let us say again that this severe form of infantile enteritis rarely occurs in the breast-fed infant.

Analgesics and the Bowel

THE most important pharmacological actions of morphine are, of course, those it exerts on the central nervous system. In relieving pain, in depressing cough and respiration, and in sometimes causing vomiting, morphine acts on different regions of the brain. But morphine also has distinct actions on some smooth muscles. For example, it increases the tone and amplitude of contraction of the ureter, it raises intrabiliary pressure by causing spasm of the sphincter of Oddi, and it has complex effects on the alimentary tract. Papaverine, another opium alkaloid, relaxes most smooth muscles, but preparations of opium such as the tincture do not contain enough to affect the action of the morphine. The synthetic analgesics, pethidine and amidone ('Physeptone'), also have distinct central nervous and peripheral actions. Both act centrally to relieve pain, but, among other peripheral effects, pethidine relaxes some smooth muscles, especially the ureter, though it raises intrabiliary pressure nearly as much as morphine.¹

The actions of morphine on the alimentary tract have been widely studied by a variety of techniques.² Its constipating effect, seen in normal people and in patients with diarrhoea, is generally attributed to direct peripheral actions on the gut. The following mechanisms may play a part in producing the constipation:

- (1) Spasm of the pyloric, ileocolic, and anal sphincters
- (2) Increase in tone, and incoördination of movements, in the muscles of the alimentary tract
- (3) Reduction in the volume of secretions into the intestine, leading to small, dry, hard stools which are difficult to evacuate
- (4) Diminished sensation in the rectum (this would be a central nervous action)

Nearly all the investigations done, whether on isolated intestine, in unanæsthetised animals, or in human beings, have shown that morphine increases intestinal tone, though ABBOTT and PENDERGRASS,³ using an intubation balloon technique in man, noted a depression of tone after initial stimulation. Constipation is an index of reduced propulsive power in the intestine, but it may be associated with either increased or reduced muscle tone. Incoördination of the activity of successive segments of the bowel will also inhibit propulsion of the intestinal contents and so tend to constipation. ADLER and colleagues⁴ made some instructive observations on ileostomy or colostomy

patients, recording pressure changes with and assessing propulsive power by measuring volume of fluid discharged from the bowel. They found that morphine caused a striking increase or abolition, of propulsive motility, though there was a simultaneous increase in tone and in non-motility. They summarised their findings by stating that morphine produces *dyskinesia* of the particularly of the colon, and such an action readily explains its constipating effect.

In Prof J. H. BURN's department at Cambridge, Dr VAUGHAN WILLIAMS and Dr STREETEN have been comparing the actions of morphine, pethidine, and amidone on the propulsive activity of the bowel in unanæsthetised dogs. They describe on p. 213 how they prepare a "Thiry-Vella" loop of small intestine which retains its normal nerve supply and blood supply through a pedicle of mesentery. Both ends of the loop are cannulated and the propulsive power of the muscle is estimated from its capacity to expel a Tyrode solution from one end of the loop to the other against a small pressure gradient. This technique provides a true measure of propulsive activity, more physiological than the insertion of a balloon catheter into the loop. The procedure does not necessarily alter the tone or non-propulsive motility of the muscle in the loop, but perhaps these components will be subjects for future study. On the whole, their results agree well with clinical experience in man, though a greater difference might have been expected between amidone and morphine. Of the three drugs, morphine is clearly most liable to produce constipation, amidone much less so, and pethidine hardly at all. The method should be useful for the study of new analgesic drugs in relation to the bowel.

How far morphine is responsible for postoperative intestinal distension or paralytic ileus is still a vexatious question, and many conflicting views have been expressed, some based on experimental work, others on clinical impressions. The use of morphine in the treatment of intestinal distension was advocated by McIVER et al.,⁵ who thought it would quieten intestinal movement. OCHSNER and GAGE,⁶ and YONKMAN et al.,⁷ who considered that the increased muscle tone was of value, particularly in preventing the development of distension. This view was also supported by CHESTERMAN and SHEEHAN,⁸ who recorded the incidence of postoperative intestinal distension in 10 patients after caesarean section. Paralytic ileus developed in 0.9% of the 340 patients who received prophylactic morphine, compared with 5% of the 160 who were not so treated. Others have supported the opinion strongly expressed by Professor BURN in his textbook⁹—that morphine favours the development of intestinal distension and is certainly contraindicated once distension has become established. KRUEGER² thought that the high pressure in the intestinal lumen produced by morphine might lead to perforation of a weakened bowel wall. FURBER reported that in man morphine increased the tone, motility, and propulsive power of the ileum, but

the inspections of persons not obviously ill was for purpose of finding faults typical of this is the criterion for life assurance, the object of which is to a reason for rejection or loading and which is due to the interests of the subject. But the object of modern school inspection is different: it is to estimate the health of the subject, to discover its trend and to point out the good and the bad points so that the former may be fostered and the latter suppressed or relieved. No one now seriously questions the value of a medical inspection though most hold that this should be given before the age of school entry. Opinion is widely divided however on the scope of the examination (as Professor Moncreiff indicated) on whether, and in what form, it should be repeated at intervals.

PERSPECTIVES IN CRIME

It is natural for the well-conducted to dislike crime, especially some types of crime, and they may not find it easy to see particular offences in relation to the general record of the country as a whole. Against the temptation to distort or exaggerate the Criminal Statistics for England and Wales, 1949,¹ are a sound corrective. The total number of people found guilty of offences of all kinds last year was 650,497—a formidable figure, on the face of it. When the figures are broken down, however, it turns out that just over half of this total number of offenders had committed non-indictable offences. Another sixth had been guilty of such offences as drunkenness, offences against by-laws and local regulations, revenue offences (mainly failure to license dogs or motor cars), betting and gaming, and offences against the Education Acts. Only 3% had been guilty of breaking and entering, only 0.8% of receiving, only 0.5% of fraud, and only 0.5% of violence against the person.

Of the total number of 650,497, only 114,294 (a fifth) had committed indictable offences, but it must be remembered, too, that the actual number of indictable offences known to the police was 459,869—more than twice the number which ended in conviction. Many offenders remain undetected or—though suspected—cannot be prosecuted (sometimes because they have died). The annual total numbers of indictable offences known to the police have in the main been rising since 1938 (when the figure was 283,220), but 1949 shows a fall of some 62,000 from the figure for 1948. Analysis of these various offences shows that larceny and breaking and entering together account for more than three-quarters of the total and that both have been declining—larceny showing the lowest figure since 1945 and breaking and entering having fallen by more than 1,000 since 1946, the peak year. Receiving, frauds, and false pretences, however, rose considerably over the 1948 figure, and so did sexual offences: these together are responsible for nearly a tenth of the whole. There were 5235 cases of violence against the person—less than one-nineteenth of the total number of the indictable offences known to the police. This figure represented an increase of 52 over that for 1948, and of 2513 over the 1938 figure, but the increase in this type of crime, though not great, has been steady.

When the numbers of those found guilty of indictable offences are analysed according to age groups and compared with the 1948 figures, an encouraging fall in juvenile delinquency is found in both sexes and in all age groups. Indeed, the figures for both boys and girls between the ages of 17 and 21 are not much higher than the figures for 1938. The most remarkable increase is in the amount of receiving undertaken by children under 14—an offence which has decreased in all the other age groups. Violence against the person rose in all age-groups up to 1948 but in 1949 it fell considerably among

children under 14 and slightly among those in the 17–21 age group. This crime is in the main committed by those in the 21–30 and the over-30 age groups. The report shows that the courts have made good use of probation, borstal training and conditional discharge for those aged 17–21. Only 15% of them were given prison sentences in the higher courts in 1949 as compared with 20% in 1948 and 23% in 1947, in the magistrates' courts only 5% were given prison sentences as compared with 11% in 1948 and 13% in 1947.

CIVIL DEFENCE AGAINST THE ATOMIC BOMB

SOME months ago we reviewed¹ American estimates of the services needed to cope with casualties from an atomic bomb. These were so elaborate and expensive as to seem impracticable: their provision would be almost a whole-time occupation for any nation. The moral might be that the time has come for all the nations to face the facts of modern life and make a correspondingly determined effort to resolve their differences peacefully. For the present, however, rearmament rather than disarmament is the order of the day and the government of any thickly populated country which is a likely target for atomic bombs would be acting irresponsibly if it did not make plans whereby the damage would be reduced.

In commenting on our leading article, Sir Ernest Rock Carling² said that no one who is conversant with the potentialities of modern weapons of war is likely to underestimate the task they would impose on the medical profession, but "there is no doubt in the minds of those who have studied the whole question intensively, that hitherto published estimates of the casualties to be anticipated in our cities are far too high." Our buildings would give more protection than most of those in Japanese cities, and the new Civil Defence manual on atomic warfare³ points out that even "the measures which proved effective in the last war, such as the warning system, the provision of shelters, schemes of dispersal and measures for preventing the spread of fire would undoubtedly reduce casualties and damage under conditions of atomic warfare." Soberly and clearly written for Civil Defence workers, the manual summarises the effects of atomic explosions under the headings of Heat, Blast and Radioactivity. Thus last, being new, in warfare and carrying persistent as well as immediate danger, is prominent in people's minds but should be kept in its proper proportion: estimates of the causes of death based on experience in Japan are heat flash 20–30%, gamma rays 15–20% and mechanical injuries and burns 50–60%. Radiation sickness and its first aid treatment are only briefly outlined in this manual. But there is much that can be done on the medical side to cure and mitigate the effects which are described. These measures will be made known in the most appropriate way to all those who require this medical and technical knowledge.

REFERRED TO ARBITRATION

THE Ministry of Health has announced that proposals for revised salary scales for medical officers employed by local authorities are to be referred to the Industrial Court for arbitration. Negotiations in the appropriate committee of the Medical Whitley Council have been unsuccessful.

Mr PETER DANIEL, consulting surgeon to Charing Cross Hospital, died at his home at Checkendon on July 28.

WE also have to announce the death on July 28 of Mr E. C. HUGHES, consulting surgeon to Guy's Hospital.

¹ *Lancet* 1950 i 263.

² *Ibid.* p. 324.

³ Atomic Warfare. Home Office Civil Defence Manual of Basic Training, vol. II Pamphlet no. 6. H.M. Stationery Office 1950. Pp. 50, 2s.

Their concentration should not exceed 0.20% and 0.10% respectively, and engines must not be used unless the ventilation in the haulage roadways suffices to keep the atmospheric concentration of carbon monoxide to not more than 0.01%. A high standard of maintenance and supervision of personnel is necessary for the successful use of diesel locomotives. These and other points are being embodied in regulations, at present in draft form.

Haulage and Winding Gear—Failures under normal loads occur most often in gear made of wrought iron and may be traceable to poor materials and bad workmanship, such as bad welding. Failures under abnormal loads are usually caused by the presence of low grade metal in the gear itself. The report condemns the custom of using a wood fire for the heat treatment of mining gear and urges the establishment of a routine metallurgical testing service for the mining industry.

Dust Investigations—"The quantitative study of industrial dusts involves two operations, the taking of a sample and its subsequent evaluation or analysis." Sampling in mines often has to be done in confined spaces with little or no illumination, thus making the use of large instruments difficult and accurate colour comparisons impossible. A variety of instruments are at present in use for dust sampling, and these are described and compared from the points of view of accuracy, "pit worthiness," and speed of estimation. Some instruments can give on the spot results with reasonable accuracy. Of all the instruments described, the thermal precipitator is the most accurate, but because of its size and weight it is not always convenient to use in a mine, and dust estimations by this method are time consuming. The Konimeter is much easier to use and gives results accurate enough for all practical purposes.

A useful appendix contains lists of lantern slides, posters, and films used in training centres.

FILM FOR LAYMEN ON CANCER RESEARCH

THE argument in favour of telling people about the prevalence, causes, and diagnosis of curable diseases is that knowledge leads to a public demand for, and cooperation in, early recognition and efficient treatment. On cancer much can be said that will relieve anxiety rather than create it, and the cinema vies with the radio as a means of gaining the attention of huge audiences. The qualifications of a good cancer film for the layman are that it shall interest, enlighten, and reassure, and that it shall condition the prospective patient to recognise possible early symptoms of the disease and to seek reliable medical advice promptly when he notices them.

A documentary film dealing with some aspects of scientific cancer research has lately been produced by the National Film Board of Canada cooperating with the Medical Film Institute of the Association of American Medical Colleges. Entitled *Challenge Science against Cancer*, it is sponsored by the Canadian Department of National Health and Welfare jointly with the National Cancer Institute of the United States Public Health Service. In half an hour it succeeds in giving the layman an inkling of the problems which cancer produces, and of some of the complexities involved in applying pathology, biochemistry, genetics, statistics, embryology, and radiology to those problems. Those who see it must be convinced of the seriousness of cancer and of the activity of research organisations in pursuing knowledge of its cause and cure. But, as a layman's introduction to the scientific side of the subject, it makes no attempt to impress upon the public the common early symptoms of cancer in the commoner sites nor does it emphasise the extent to which early recognition and treatment can ensure survival or abolish discomfort. The characters in the film have little to say for themselves, and the dialogue, earnestly spoken by the Canadian film actor Raymond Massey, is consonant with the solemnity of the subject. The pathetic expressions on the faces of the patients, and the brow-wrinklings of the laboratory workers are well calculated to wring the hearts

(and purses) of a sensitive audience. Animated designed to illustrate the detail of cell processes made at sufficient magnification to create the complicated physicochemical molecular universe, the musical accompaniment to these chemical equally unearthly.

This film will not bring to their doctors more with adventitious lumps, abnormal vaginal persistent ulcers, coughs with hæmorrhage, or constipation, but it will show the public that the world is very far from idle about cancer; and it to the medical profession that films can be which make even some of the more abstruse cancer intelligible to the laity.

Copies are available in 16 mm width from the Film Board of Canada, Sackville House, 40, Piccadilly (Tel. Regent 5205).

SCHOOL MEDICAL INSPECTION

At the Liverpool meeting of the B.M.A., Prof. Moncreiff argued that routine medical examination of school children is a waste of effort, and that the time could be used in other ways to the greater benefit of the children. His remarks recall a paper which Dr. I. Gordon, now M.O.H. for Ilford, read at the pros and cons of such examination.

When the Education (Provisions) Act of 1907 obliged education authorities to arrange for medical inspection in elementary schools, the immediate object was to discover diseases and defects for which the child should have treatment, and to advise the parent accordingly. This was the first example of medical supervision of a whole unselected section of the community, and it aimed at prevention as well as remedy. At the beginning of the century modern preventive medicine hardly existed, and at first, therefore, the of medical inspection was almost wholly curative. "Static" examination was devised to distinguish diseased from the healthy, the former being advised to obtain treatment, while the latter were passed as healthy. We were yet to learn that this division was arbitrary, that most of us are neither sick nor healthy, but maintain a precarious position between the two states. Static examination, unless very elaborate, reveals nothing but obvious lesions, the results of pathological processes, it gives prominence to structural departures from the usual, which may or may not have consequences, but it fails to reveal the state of health and the way in which it is trending. Important though it is as a beginning of supervision, it can be no more for health and disease do not stand still.

At first, and to some extent still, school medical inspection was looked on as the lowest grade of public health and a mere stepping stone to something better, but who undertook it saw that it could be perhaps the best expression of medical craft. There are still in the school medical inspectors, who have seen it change from a mere scheduling of defects to an intelligent supervision of the child's health during the period of development. As the conception altered, they discovered how much was known about the physiology of childhood and the way in which people react to the stresses of environment, and the great increase of knowledge in the past thirty years owes much to the disclosure of our ignorance.

Dr. Gordon, asking whether harm is done by routine inspections, pointed out that "the injudicious use of medical examinations may implant a neurosis by unnecessarily emphasising some harmless or mild condition." Before the inspection of school children was started, the

1 Dawson Williams lecture to the Section of Child Health reported on p. 222.
2 *Brit. J. Soc. Med.* 1947 1 238

TON saw danger in teaching induction for these

Diagnosis of Early Pregnancy

F E STARLER, in an interesting and entertaining way, argued that when properly used clinical methods could prove just as accurate as the biological tests, discussed several signs not generally sought, and the value of percussion. Other speakers also considered the patient's symptoms important, and the diagnostic significance of a slight rise of temperature was mentioned.

menopausal Bleeding

Professor A M CLAYE defined this as bleeding in a non-pregnant woman after at least six months' amenorrhoea. In the periods had previously been regular. As a third of these patients had malignant disease, a full investigation was always necessary. Carcinoma of the cervix was the most important cause, but bleeding associated with a uterine polyp was common. The first condition found on examination might not be the most serious one. Much diagnostic trouble was due to the use of oestrogens, these should only be given with a good reason, and norethisterone was often as effective. Several speakers referred to the difficulties caused by the use of oestrogens.

DISEASES OF THE CHEST AND TUBERCULOSIS

President Mr H MORRISTON DAVIES

section of Lung for Pulmonary Tuberculosis

Dr D F THOMAS based his remarks on an analysis of 200 resections performed by Mr Ronald Edwards and his associates at the Liverpool centres. Published results, he said, differed widely, since some dealt with the treatment of minimal lesions and others with the "maximal" disease. His series was very definitely in the former category. In 30% of thoracoplasties cavity closure was not achieved, but so far 93% of their 10 patients had negative sputums after operation. The mortality had been only 2.5%, which is an extraordinarily creditable figure.

Their chief indications for resection were as follows: tuberculosis, bronchiectasis, empyema with fistula, indications with which few would disagree, and bronchocarcinoma and "failed thoracoplasty." He made the important point that resection should not be contemplated for bilateral disease unless the contralateral lesion was known to have been quiescent for at least a year, and he finished by emphasising that the series was experimental and no firm conclusions should be drawn for at least five years, but that the short term results were most encouraging.

Mr RONALD EDWARDS said he was sure that if a non was not palpable it was safe to leave it. Measures to prevent over-expansion of the remaining lung tissue could include phrenic crush or avulsion and pneumothorax maintained for three months after lobectomy or a modified thoracoplasty, leaving the first rib in situ after pneumonectomy.

Mr JOHN BICKFORD analysed the series, of which 100 had been followed for over a year, and 100 for six months. There had been 10 empyemata and 6 fistulas in the first 100 cases, and only 6.7% had a persistently positive sputum. Of these patients, 55% would previously have been considered suitable for thoracoplasty, and there seemed little difference in the late results of those suitable and those unsuitable for this operation.

Mr J R BELCHER said he felt that resection should be confined to patients with some only of the indications outlined by Dr Thomas, agreeing that it was ideal for upper lobe cavitation, and adding acute ruptures of a cavity as another indication, but all other cases suitable for surgery, particularly where disease was bilateral, should be subjected to thoracoplasty. Using this yard-

stick, Mr Holmes Sellors and his assistants were performing six times as many thoracoplasties as resections.

Pain in the Chest

Dr DONALD LLEMMING said that pride of place in the causation of this symptom was taken by cardiovascular disease. In enumerating some of the many other causes, he emphasised the importance of liver abscess and amoebic hepatitis. Dr RHODES ALLISON reaffirmed the importance of cardiovascular disease, and described its association with left shoulder pain and periarticularitis—a syndrome mentioned by several other speakers. He also insisted that fibrositis of the chest wall was a clinical entity. Dr J L LIVINGSTONE described, from personal experience, very widespread pain due to fractured ribs, and also mentioned spasm of the intercostals and of the triangularis sterni as a cause of pain in emphysematous patients.

MEDICAL GENETICS

President Dr C P BLACKER

Contribution of Genetics to Medical Practice

The introduction of this new section was something of an event for the small band of medical geneticists. It expressed their feeling that human genetics was approaching the stage where it would be able to offer the general practitioner practical help in dealing with the problems of the families under his care.

The most obvious practical application of human genetics to medical practice is, of course, the analysis of the blood groups in relation to hemolytic disease of the newborn. Dr R R RACE told the meeting that once a Rh negative woman (or even baby girl) was immunised then all her subsequent Rh positive children would be affected, the proportion of Rh positive children depending on her husband's genotype. Fortunately a pregnancy with a Rh positive foetus was a relatively inefficient method of immunisation, and in only 10% of the marriages at risk were there affected children. But a transfusion or even a small intramuscular injection of Rh positive blood would immunise about 50% of Rh negative women, this was maltreatment.

Prof L S PENROSE, who introduced the discussion, drew attention to another field where genetic studies showed great promise. This was the group of disorders to which Sir Archibald Garrod gave the title "inborn errors of metabolism." Here the relation between gene and clinical disorder was often as close and exact as with the blood groups. Combined biochemical and genetic studies gave a precise meaning to the old concept of diathesis, and in time would give the practitioner the opportunity to institute early and effective prophylaxis.

Dr J A FRASER ROBERTS showed that quite apart from the instances where genetics was important in diagnosis and treatment, it was of practical value in a wide range of diseases in giving advice to individual parents with an affected child who wanted to know if further children were likely to be affected in the same way. For the past three years he had held a "clinic for genetic advice" at the Hospital for Sick Children, Great Ormond Street. While the serologists, he said, knew the genetics of their subject backwards and needed no help from the geneticist, for some time to come neither the general practitioner nor the specialist would often have sufficient knowledge of the scattered and difficult literature to give parents the best genetic advice. It was his experience that in the majority of instances it was possible to give the parent a reasonable estimate of the outlook for further children. It was for the parents themselves to decide whether they would take the risks of having further children. He thought that there would be scope for genetic clinics in every large city, if someone could be found to run them.

BRITISH MEDICAL ASSOCIATION

Scientific Sections

OBSTETRICS AND GYNÆCOLOGY

President Mr ARTHUR GEMMELL

The meetings of this section took place in the engineering building of the university, and some speakers thought that this provided a very appropriate atmosphere for some of the subjects under discussion.

Tuberculosis and Pregnancy

Mr J A STALLWORTHY emphasised the importance of unsuspected endometrial tuberculosis, which was found, he said, in 2-5% of curettings. The classical symptom of amenorrhœa was uncommon in these cases, and more than half of them had some increase of menstruation. Both bacteriological and histological tests were necessary for diagnosis and for proof of cure, and he referred to the work of a committee now investigating the effect of streptomycin treatment, which held that three negative tests at monthly intervals were essential before cure could be presumed. Infection might spread in a symptomless case, and the only death in 48 patients who had been seen at Oxford occurred in one such patient who refused treatment. Sanatorium treatment was unsatisfactory, and hitherto the only cures had resulted from radical surgery, but the use of streptomycin combined with *p* ammosalicylate had produced apparent cure in 5 cases out of 6, and this treatment could be carried out at home. If, however, it did not bring improvement, radical surgery should be resorted to.

In the discussion several cases were quoted in which apparent cure or improvement followed the use of streptomycin, and two speakers referred to the exacerbation sometimes seen in pelvic tuberculosis after diathermy.

Dr R C COHEN, in a paper on Phthisis and Pregnancy, said that there was no evidence that pregnancy had any harmful effect on tuberculosis if good treatment was given. Of 335 active cases in pregnancy which had been admitted, only 35 had retrogressed, and this was little more than the expected rate. He felt it difficult to justify the use of therapeutic abortion, but admitted that social factors also had to be considered here. Radiography should be carried out as a routine in pregnancy. In the treatment of active disease in the pregnant woman, attention to secondary anaemia and to the mental condition was important. Inhalation anaesthetics, including gas and air, could be given, a long second stage should be avoided, and caesarean section should be resorted to for disproportion to a greater extent than otherwise and in cases of tuberculous laryngitis. The use of artificial pneumoperitoneum after delivery had no physiological justification, but the use of an oestrogen was important. Streptomycin could be given without any increased risk of reactions or harmful effect on the baby.

In the discussion Miss PHILLIS DINGLE referred to the rapid deterioration that sometimes followed delivery, and said she was convinced of the value of an artificial pneumoperitoneum. It was essential to use a large volume—as much as 3000 c.c.—of a mixture of oxygen and air. Other speakers laid stress on the favoured conditions under which Dr Cohen's patients were treated, on the importance of social circumstances, and on the difficulty of getting patients into a sanatorium.

Prevention of Prolapse

Prof R A LENNIE said that, although in a series of 300 cases of prolapse in instrumental delivery had been carried out in 47%, he thought the most important factor in prolapse was an inherent weakness. The timely use of forceps was justifiable as a prophylactic measure, especially in transverse arrest of the head.

Proper manual rotation was important, but rotation was to be condemned. The use of the forceps might be dangerous, especially in the novice. The use of forceps on the aftercoming head was also important. The risk of an episiotomy was a sudden descent of the head must not be overlooked.

Mr J D FLEW believed that too much emphasis had been laid on having an intact perineum after delivery. An episiotomy prevented ragged tears, facilitated obstetric manipulations, and decreased maternal and foetal damage by relieving the strain on the tissues. It was especially valuable in preventing damage to the anterior vaginal wall, where many symptoms could arise.

Mr BRYAN WILLIAMS, speaking on Delivery Repairs, said that though there was a risk of it if delivery took place after a repair, he did not think sufficient to justify the postponement of treatment in young patients whose symptoms were troublesome. The cervix, however, should not be amputated, for this often led to serious complications in pregnancy and labour, and the teaching of Fothergill himself on this matter had been much neglected. Apart from cases in which the cervix had been amputated, caesarean section was seldom indicated. But the patient who had had repairs must be delivered in hospital, for often she would need either instrumental delivery or episiotomy with a full repair.

Mr R NEWTON described the pioneer work of Mr Heardman on antenatal exercises, and gave the results of a controlled investigation into the effects of exercises on the course of labour and the subsequent incidence of prolapse. He reluctantly came to the conclusion that these exercises did not reduce the incidence of prolapse though they did result in a more normal labour.

In the discussion on these papers attention was turned to the paradox of why prolapse seemed uncommon in the American woman, who so often underwent forceps delivery and episiotomy, and also in the Bantu woman, whose labour was so seldom aided in these ways. Among those who discussed these points were Prof E C CRITCHER (Cape Town), Dr J SNYDER (Philadelphia), and others who had worked in Africa. Mr GORDON LENNIE maintained that no novice should treat occipitoposterior positions, and Mr C M MARSHALL stated that it was far more important that a biparietal application of forceps should be made than that any particular instrument should be used. Mr Flew thought that when exercises were done the obstetrician should supervise them himself, for otherwise they might be risky. A suggestion that the exercises should be demonstrated by Mr Newton and the Chairman (Mr Charles Read) was strongly resisted.

Postmaturity

Mr C J K HAMILTON and Mr WILFRED MILLS both regarded postmaturity as a definite entity carrying but risk for the foetus and often needing interference. Mr Hamilton referred to Barcroft's work which showed that a certain crisis was reached in intra uterine life and the foetus must 'escape or die'. Foetal distress had been observed in a high proportion of the cases investigated by him, and he therefore favoured rupture of the membranes when there was a reasonable certainty that term had been reached, and felt that there was no place for the use of quinine or pituitary extract. Mr MILLS said that postmature babies might show excessive size or sometimes retarded growth, and asphyxia, and favoured the extensive use of induction when term had been passed. In the discussion there was a fair amount of disagreement with the speakers' views, and Professor

æa and vomiting. Infections encountered in the 1" wards amounted to 2% of all admissions, and they were not usually fatal; they represented a considerable reduction in the beds available. With the increased use of intravenous therapy there had been a decrease in the incidence of drip sepsis, amounting to 12.5% in 1949, but by adherence to surgical aseptic technique the incidence of this type of infection could be considerably reduced. The dangers of respiratory and intestinal infections in children admitted to day nurseries were emphasised by R. K. M. HIRST, and one speaker described day nurseries as State sponsored centres of infections. Dr RYLE gave an account of the commoner infections encountered in schools, including influenza, streptococcal throat, otitis media, and glandular fever.

Physical Care of the Physically Handicapped Child

Dr C. D. S. AGASSIZ said that handicapped children should be treated as far as possible as normal children. While in hospital, they benefited from frequent visits, not only from parents but from their brothers, sisters, and friends. They should receive education while in hospital, attending a classroom in the grounds for this purpose; this would not only encourage mobility but would also give them a more normal mental outlook. Dr AGASSIZ also favoured television sets in the hospital ward as an admirable suggestion if funds can be found. Dr H. M. COHEN urged regional rather than parochial nursing, and the psychological aspects were discussed by Dr ALAN MABERLEY, who advocated rest, protection of the environment, and encouragement for these patients. He warned against making illness so attractive that physical symptoms were exploited. Dr MARY SHERIDAN recounted examples of the clinical histories of children suffering from high tone deafness, and showed how this defect simulated mental deficiency.

ANATOMY AND PHYSIOLOGY

President Prof A. DURWARD

Lymphatics

The meeting of this section opened with a film on the *Lymphatic System* by Prof J. M. YOFFEY. The primary purpose of this film was to demonstrate functional lymphatic pathways in different parts of the body. A considerable part was devoted to the cervical lymphatic pathway draining the mucous membrane of the nose and pharynx; this pathway was demonstrated in the cat, dog, and monkey by the absorption of a vital dye after nasal instillation. The film brought out clearly the presence of a chain of small lymph glands in the cervical pathway of the monkey—similar to that in man—as opposed to a single large gland in the cat and dog. It also demonstrated the ease with which the tonsillar and palatal lymphatics, as well as the entire cervical pathway, could be filled after the injection of a tracer intracranially into the subarachnoid space.

Skin Grafts

Prof. G. M. WYBURN pointed out that homografts tended to give a higher proportion of failures than was generally appreciated. There were some interesting observations—on notably cornea and cartilage, which contained a considerable amount of non-antigenic polysaccharides. One of the striking features about the skin graft was that, while it retained some of its original characteristics, it also acquired in some respects the characteristics of the recipient area. Professor Wyburn illustrated this by reference to sensation and sweating in skin from the abdominal wall grafted on to fingers or on the hand, ultimately to acquire the sensory pattern, at any rate as far as touch was concerned, of the surrounding skin. He thought it probable that the ingrowing nerves determined the resulting sensory pattern, perhaps

even furnishing their own sense organs. Furthermore, the nerves growing into the grafted skin were projected on to a much larger area of the sensory cortex. The sweat glands remained anatomically unchanged, but the type of sweating might change radically, and abdominal skin, where sweating was primarily a thermal response, would after grafting on to the fingers develop an emotional type of sweating. Thus, too, almost certainly depended on altered nervous connections, and not on any change in the sweat glands themselves.

Histology and Physiology of the Adrenal Cortex

Dr M. H. POWER (U.S.A.) reported on studies of patients with hyperfunction and hypofunction of the adrenal cortex. He first distinguished between Cushing's disease, in which there was a basophil adenoma of the anterior pituitary, and Cushing's syndrome, in which there was hyperfunction of the adrenal cortex with or without an adrenocortical tumour. Dr H. L. MASON had definitely established that with hyperfunctioning adrenal glands excretion of urinary corticosteroids was increased, and had recently isolated crystalline 17-hydroxycorticosterone (Kendall's Compound F) from the urine of a case of Cushing's syndrome. Dr Power thought that this was the first instance of the isolation of an adrenal steroid from human urine, and on the basis of this and other evidence it seemed quite possible that Compound F might be the principal steroid elaborated when the adrenal gland was stimulated by adrenocorticotrophic hormone (A.C.T.H.). Probably Compound F acted much like 'Cortisone,' though possibly larger amounts might be required to achieve some of the effects of the latter. Cortisone or A.C.T.H. were capable of producing many of the signs and symptoms of Cushing's syndrome, including alkalosis.

Dr Power described findings in patients with Addison's disease. While cortisone was not altogether without influence on the course of electrolyte excretion, it was not as effective as deoxycortone acetate. On the other hand, the ability of patients receiving cortisone to withstand the apparently severe electrolyte depletion and hæmoconcentration, with extremely low plasma sodium, emphasised the validity of the earlier work of Swingle and his associates, who had pointed out that the electrolyte changes per se might not be the primary factors in the fatal collapse of the adrenalectomised animal. In a patient in whom deoxycortone had been replaced by cortisone, there was a condition of dehydration and hæmoconcentration which seemed to be typical of Addisonian crisis and should have been associated with falling blood pressure and collapse, but blood pressure had been well maintained, and the patient appeared far from collapse.

Mr K. C. RICHARDSON discussed some structural aspects of the adrenal cortex. Since the isolation of the steroid hormones, much effort had been expended on their detection *in situ*. But unfortunately they were discharged from the cortex almost as rapidly as they were formed, and the histochemist was forced to attempt the identification of mere traces. Mr Richardson emphasised the peculiarities of the adrenal circulation, as a result of which it was conceivable that adrenaline formed in the medulla might have ready access to the cortical cells, coming first into contact with those of the zona reticularis. He doubted whether the zona glomerulosa could be regarded as an immature zone which gave rise to the fasciculata and reticularis, and he referred to the alternative view that there was a narrow, indifferent, intermediate zone, between glomerulosa on the one hand and fasciculata and reticularis on the other, capable of proliferating in either direction. This was the sudanophobic zone. However, while the glomerulosa and the fasciculata showed a relatively high frequency of mitotic division, mitoses were not entirely

Both Professor Penrose and Prof F A E Crew, FRCS, touched on the wider question of eugenics. Professor PENROSE put forward the view that at present the prospects of making any appreciable change in the genetical composition of the population were remote, and that such an aim, directed towards improving the health, not of the existing population, but of future generations, was hardly consistent with the fundamental medical tradition of treating every individual case on its own merits. Professor CREW, on the other hand, held that the leaders of the medical profession should firmly declare that medicine was concerned not only with the health, happiness, and efficiency of individuals of the living generation but also with such as are yet unborn. Medical genetics, he suggested, could become an instrument of precision that could be used with advantage in the preventive field.

Dr W N PICKLES said that the general practitioner who had been long in one district saw clearly the trend of hereditary factors in disease, especially of common diseases. He knew of one family of 62 persons, 23 of whom had had rheumatic fever or unmistakable signs of mitral disease.

CHILD HEALTH

President Prof N B CAPON

When the B M A last met in Liverpool, in 1912, the title of this section was Diseases of Children including Orthopaedics. The change of name reflects the advances made in paediatrics (and orthopaedics) in the past 38 years.

The chair of child health in Liverpool was established in 1944, and visitors were able to see the headquarters of the child health department at Alder Hey Children's Hospital where a clinical meeting was held, with demonstrations of tuberculosis and rheumatic infection. In addition, there were five other meetings of the section—the largest number held by any section. Throughout these meetings two important aspects of paediatric practice were emphasised—the vital rôle of the general practitioner, and the necessity for continuity of observation and treatment if reduction of mortality and morbidity is to be achieved and full health maintained. The coordination of services, so often lacking, is well advanced in Liverpool. For 25 years a paediatric physician has been on the staff of the Liverpool Maternity Hospital and this liaison has now been extended to all the neonatal units in the city. Furthermore, there is active collaboration between the child health department and the doctors in the departments of infant welfare and school health.

In his Dawson Williams lecture, Prof ARAN MONCRIEFF reviewed the changes in the pattern of disease in infancy and childhood during the past half century, and suggested that in consequence of these changes the work undertaken by the infant welfare clinics and by the school health service should be reorientated. The infant welfare clinics might well concentrate on the prevention of tuberculosis, on the prevention and control of respiratory disorders, and on educative measures designed to prevent accidents on the roads and in the home. He thought that routine school inspections by the medical officer were of little value and that a competent nurse would detect early variations from the normal. If routine medical inspections were discontinued, the doctor could undertake the more important work of health education by helping to plan the school syllabus, by teaching biology and giving sex instruction, by supervising the hygiene arrangements, school meals, &c., and by investigating such problems as the causation of postural defects and how these responded to different forms of treatment.

Breast feeding

Dr CHARLOTTE NAISH emphasised the continuity of treatment which the general practitioner could give

during the antenatal, natal, and postnatal periods. She deprecated the prevalent compartmentalism in branches of medicine and surgery. She thought stress should be laid on three important aspects—breast feeding—research, comparative animal and human (a word she preferred to pet), and the use of the right words might have a profound effect. Complementary feeding should be called topping and breast feeding would be more popular if the nutritive fluid were called cow's juice rather than milk. Two clubs—one for mothers and the other for fathers which thrive in Dr Naish's practice have a influence on both doctor and patient.

Dr K C RICHARDSON described the neurohormonal mechanism responsible for the discharge of milk from the breast. His paper, describing the action of the myoepithelial cells, was a notable contribution to the literature of breast feeding, and the histological section was of the highest order.

Dr H K WALLER said that tension in the breast often caused diminished milk production and described the measures necessary in the last months of pregnancy to prevent the onset of tension. His remarks were illustrated by a coloured film. In the general discussion "rooming in" and "self demand" feeding were mentioned by several speakers, and the general consensus of opinion was that all extremes should be avoided and that each baby presented an individual problem.

Surgical Conditions in the Newly Born

Mr DENIS BROWNE said that paediatrics was now firmly established as a specialty, and the care of children was no longer in the hands of the general physician. The next logical step was to set up centres of neonatal surgery, with a surgeon in charge having special knowledge of neonatal disorders—a surgeon, in fact, in care for a particular age period rather than for disorders of a particular organ of the body. Special apparatus, special wards, specially trained nurses, and anaesthetists skilled in special anaesthetic techniques would complete the team.

Mr R H FRANKLIN discussed some of the congenital abnormalities of the alimentary tract, particularly the oesophagotracheal fistulas, and described in detail the diagnostic procedures, the preoperative and postoperative measures, and the prognosis, which to a large degree depends on early diagnosis.

Dr JACKSON REES spoke of the value of hyperventilation and endotracheal tube, which ensured good operating conditions for the surgeon, as little interference as possible with the vital processes of the child, and protection of the child against accidents such as collapse of a lung, which might occur during the operation.

Epidemiology in Relation to Child Health

Prof STANLEY GRAHAM said that, of the four main causes of death in the neonatal period, infection was the one which the paediatrician could influence the most. The common minor infections encountered were conjunctivitis, pemphigus, and thrush, and the most serious infections usually met with were respiratory disorders and epidemic diarrhoea. Measures designed to prevent these infections and to prevent premature birth would noticeably reduce neonatal mortality.

Dr W N PICKLES described the infections encountered in the home. Tuberculosis was the most important infectious disease and he vividly described its role in a family in his practice. He has records of 6000 cases of infectious illnesses occurring in his practice during the past nineteen years.

Dr R M TODD described the infections occurring at Alder Hey Children's Hospital during 1940, and emphasised the dangers to infant life and health resulting from cross infection, particularly from an outbreak

INTERNATIONAL CANCER CONGRESS

the fifth International Cancer Congress, which was in Paris at the Sorbonne from July 16 to 22, under presidency of Prof. A. LACASSAGNE, was opened by M. VINCENT AURIOL, President of the French Republic. Organised by the International Union Against Cancer with the collaboration of the French League Against Cancer and UNESCO, it was attended by representatives from more than 50 countries.

A wide range is indicated by the following list of sessions before which numerous individual papers were presented and discussed: Tumours and Hormones, Tumours and Viruses, Experimental Chemotherapy, Radiotherapy, Transplantable Tumours, General Pathology, Induced Tumours, Tumours and Microorganisms, Nutrition, Cytology and Histology, Biophysics, Radiobiology, Protection against Carcinogenic Agents, Male Genito-Urinary Cancer, Cancer of the Respiratory Tract, Cancer of the Alimentary Tract, Cancer of the Salivary Glands, Cancer of the Breast, Cancer of the Uterus, Cancer of the Bone and of the Blood, Cancer of the Nervous System and Cancer of the Thyroid, General Pathology, Social Aspects of Cancer, and Miscellaneous Communications. Colloquia were also held each day in which leading workers were invited to discuss their personal conception of the subject under review.

Several films on technical and other (e.g., popular education) aspects of cancer were shown during the congress. Other exhibits included cancer education and cancer control in different countries and an ambitious scheme to index the names and interests of cancer research workers throughout the world, and to make microfilms of their publications readily available.

The reports of the congress will be published during the next few months in issues of the *Acta Unionis Internationalis Contra Cancrum* (obtainable at a cost of 10 dollars from Professor Maisin, 61, Voer des Capucins, Brussels, Belgium). The next (sixth) International Cancer Congress will be held in Brazil in 1953.

Communications

ETIOLOGY

Recent work by Gye, Craigie, Mann, and Begg has suggested that as mouse sarcoma could be transmitted by frozen and desiccated tumour tissue this was evidence that a virus was the agent responsible for the tumour growth if it were assumed that the freezing and drying had killed all the original tumour cells. R. D. PASSEY, D. MOCHOWSKI, and I. GLUCKSMANN (Leeds) reported that some cells could survive after freeze drying of mouse mammary tissue, and that this could be demonstrated by microscopy and by the growth in vitro, by tissue culture technique, of frozen and desiccated tumour tissue. I. HEGGER (London) also failed to confirm the work of Gye et al. and felt that their results could be explained upon such lines as "imperfect dehydration leaves some cells or fragments of tumour with sufficient ability to grow in the new host." J. E. GREGORY (Birmingham) had no doubts about the rôle of viruses in cancer, he claimed (see also *Erper Med Surg* 1948, 390) that electron microscopy of biologically filtered extracts of malignant and other tissues revealed objects of similar cell structure only in malignant tissue and not in normal or benign tumour tissue. He also reported that an antibiotic produced by *Bacillus subtilis* had an inhibitory effect on malignant tumour growth. R. D. PASSEY, I. D. MOCHOWSKI, W. ASTBURY, R. REED, and J. JOHNSON (Leeds) reported that electron microscopy of extracts of any tissue (e.g., mammary tumour, milk) shown to contain the mouse milk factor revealed large numbers of particles which were absent or only present

in insignificant numbers in similar extracts from mice of low breast cancer strain.

I. C. DILLER (Philadelphia) found spores and other fungal structures in specially stained smears from almost every case she examined of a variety of mouse tumours (e.g., leukaemias transplantable and induced sarcomas, spontaneous mammary carcinomas) and human tumours (mammary carcinomas, lymphadenomatous glands, sarcomas). A yeast or yeast-like organism appeared to be the culprit, and injection of such freshly isolated organisms into mice caused death within 4-5 days. N. MORI (Naples) and F. GERLACH (Santiago) also reported a relation between cancer and fungi.

Tobacco smoking and cancer of the lung were discussed by E. L. WYNDER and C. A. GRAHAM (St. Louis), A. OCHSNER (Albany), and M. LEVIN (Albany). All agreed that there was a significantly higher incidence of lung cancer in heavy smokers, particularly cigarette smokers. Lung cancer was more common in men than in women, in women, however, the incidence was also far higher in cigarette smokers than in non smokers. LEVIN also reported a positive relationship between lip cancer and pipe smoking. WYNDER and GRAHAM stressed that a moderation of smoking habits, especially of cigarette-smoking, was desirable, the identification and elimination of possible carcinogens in tobacco was clearly important as well.

A possible relation between circumcision and cancer of the prostate was suggested by A. RAVICH (Brooklyn) who found a lower incidence of prostatic cancer in circumcised males, and recommended circumcision of all males during infancy as a safe and feasible means of reducing the incidence of prostatic and penile cancer as well as cancer of the cervix in females.

CHEMOTHERAPY

Large scale "screening" trials of compounds for possible tumour inhibitory activity were reported by British and American workers. C. C. STROCK and his associates at the Sloan Kettering Institute, New York, tested large numbers of compounds (e.g., nitrogen mustards, ethylenamines, folic acid analogues, steroids) against a "spectrum" of mouse and rat tumours. Promising compounds discovered in this manner were those containing ethylenimine groups and possessing biological activity similar to that of the nitrogen mustards. The tumour inhibitory effect of substituted melamines was also detected by biological screening methods by J. A. HENDRY, F. L. ROSE, and A. L. WALPOLE (Manchester). E. PATERSON and J. BOLAND (Manchester) reported the results of clinical trials with trimethylolmelamine and an ethylenimine derivative. D. A. KARNOVSKY, J. H. BURCHENAL, J. L. BERNSTEIN, and C. M. SOUTHAM (New York) also reported the results of clinical trials with triethylene melamine. These compounds, particularly the freely soluble triethylene melamine, may eventually replace the nitrogen mustards. The therapeutic effects are similar, but there is far less nausea and vomiting, and the drug may be given orally. KARNOVSKY and his associates emphasised that triethylene melamine was a very dangerous drug and was 2-3 times as active as the nitrogen mustard methyl bis(β -chloroethyl) amine hydrochloride. Particular care was needed in cases of lymphatic leukaemia.

M. B. SHIMKIN (San Francisco) pointed out that as 20% of cases of myeloid leukaemia lived 4-5 years without any form of treatment care should be taken in assessing the activity of chemotherapeutic substances in this disease on a survival time basis.

J. M. STICKNEY and W. A. BENNETT (Rochester) studied the effect of cortisone and adrenocorticotrophic hormone (ACTH) on acute leukaemia, and reported that in most cases the patients did not respond to this therapy.

lacking in the reticularis. No final opinion, therefore, could yet be given on the relation between the main cortical zones from the point of view of cell growth. The suggestion that the glomerulosa had as its function the secretion of steroids without oxygen at C_{11} was difficult to reconcile with the concept that it was an immature part of the cortex which provided cells for the actively secreting zona fasciculata. He felt that all that could justifiably be asserted was that the outer cortex had a high growth potential, but the actual rate of growth in the intact gland, and what happened to individual cells, remained uncertain.

Dr G. W. HARRIS discussed the neural regulation of A.C.T.H. secretion by the anterior pituitary gland. Three theories had been advanced to account for the control of A.C.T.H. secretion. Long's adrenalhine hypothesis suggested that circulating adrenalhine played an important part in stimulating the output of A.C.T.H., particularly after stress. However, Dr Harris doubted whether adrenalhine was of more than minor importance, for stress secretion of A.C.T.H. could occur in rabbits whose adrenal glands had been denervated, as also in dogs which had been completely sympsectomised, such animals also responded to electrical stimulation of the hypothalamus. Then there was the view of Sayers and Sayers, that there was an inverse relation between the level of cortical steroids in the blood and the secretion of A.C.T.H. According to this hypothesis, the action of stress in stimulating A.C.T.H. output was indirect, stress first caused increased utilisation of steroid hormones by the tissues, after which the pituitary responded to their diminished level in the blood by further production of A.C.T.H. This theory was plausible as far as acute stress was concerned, but it broke down over prolonged stress, for after the initial response the steroid content of the blood would rise and automatically depress any further secretion of A.C.T.H. Dr Harris summarised experiments by himself and others which seemed to show quite clearly that secretion of A.C.T.H. could be evoked by stimulation of parts of the hypothalamus—namely the posterior region of the tuber cinereum and the mammillary bodies. Furthermore, destruction of these regions abolished the response, which was measured indirectly by the fall in the blood lymphocytes. A similar view had been advanced by other workers using the fall in the circulating eosinophils as a criterion. Dr Harris felt that, under quiet conditions, the level of the blood steroids, and also the adrenalhine content of the blood, played some part in regulating the output of A.C.T.H., acting either directly on the pituitary or via the hypothalamus. When stress supervened, however, neural influences exerted on the anterior pituitary via the hypothalamus would seem to take precedence over the other mechanisms.

Dr M. VOOR pointed out the difficulties of assessing cortical activity. Hormones could not be estimated in the cortex itself, for it rapidly discharged its secretion into the blood. Studies of the cortex itself could therefore only throw indirect light on the problem, through the estimation of chemical or histological changes known to be associated with cortical activity, such as the fall in its cholesterol or ascorbic acid content. However, it was possible to attempt direct estimation of steroid hormones in the venous blood leaving the adrenal glands, through an elaborate method of biological assay. Furthermore, prolonged stimulation of adrenal cortical secretion might result in frank hypertrophy. Clinically, some guide to cortical activity could be obtained from the effects of the cortical hormones on the level of the blood eosinophils or uric acid, or capillary fragility. Finally, the end-products of the steroid hormones could be assessed in the urine.

Adrenal secretion could be stimulated in a variety of ways, which for convenience were included in the general term "stress". One of the responses to stress was

increased secretion of A.C.T.H. by the pituitary, and the organism thereby was provided with increased amounts of cortical hormones. Apart from its importance in stress, A.C.T.H. maintained the adrenal cortex in its condition.

The question then arose: was the adrenal cortex completely dependent on the formation of A.C.T.H. by the pituitary? Here caution was needed. For instance, there were some rather significant species differences. Thus the pigeon responded to insulin even after hypophysectomy. Atrophy of the cortex was evident after 5 days in the rat, but after 1 month in the dog, and not all layers of the cortex atrophied, for the glomerulosa after hypophysectomy remained normal or even hypertrophied somewhat.

Could the adrenal cortex adapt its secretion to the body's requirements by any other means than the secretion of A.C.T.H.? The answer could be obtained from the isolated perfused adrenal, which secreted considerable amounts of hormone even if perfused with blood devoid of A.C.T.H., and even if taken from a dog which had been hypophysectomised some time previously. Under such circumstances there was a basal steroid output, which had so far been markedly increased in two ways. The first was by alteration in the electrolyte content of the blood, excess of potassium causing increased secretion. The second was by perfusion with a source of readily available energy, such as adenosine triphosphate and related compounds.

Professor YOFFEY then discussed the relation between the adrenal cortex and the lymphoid tissues. It had long been known that there was some relation between the adrenal cortex and the lymphoid tissues, and lately the problem had been intensively studied by Dougherty and White. Their main thesis was that a number of steroid hormones oxygenated at C_{11} produced varying degrees of damage to lymphocytes, resulting in regressive changes in the lymphoid tissues as a whole and lymphopenia. As a result of lymphocyte dissolution and possibly also by a mechanism of secretion, increased quantities of gamma globulin and antibodies were discharged into the blood stream, and played an important part in the body's immunity reactions. The increased formation of gamma globulin in response to cortical hormones and A.C.T.H. had not been confirmed by other workers, while as far as the regressive changes in lymphoid tissue were concerned, the evidence was very mixed. It means as clear cut as it at first sight appeared. The trend of recent work had been to implicate the plasma cell rather than the lymphocyte in antibody formation, while no action of cortical hormones could be shown upon lymphocytes in vitro.

He then referred to some recent experiments he had conducted in collaboration with W. K. Metcalf and J. Nairn, with the statistical assistance of G. Herdan. As a quantitative technique for the estimation of nucleated cells of bone marrow, it was found that guinea-pig that 6 hours after intraperitoneal injection either an aqueous cortical extract or A.C.T.H. there was a statistically significant increase in the lymphocyte content of the bone marrow. The lymphocyte count increased from a normal of 142,000 per c.mm. of marrow to an average of 203,400 per c.mm. after A.C.T.H., and 269,000 per c.mm. after cortical extract. Furthermore, the number of damaged cells actually diminished when compared with those obtained in normal marrow. It seemed probable, then, that one of the factors responsible for the lymphopenia induced by cortical hormones and A.C.T.H. was an increased uptake of lymphocytes by the bone marrow. The significance of this was not clear, but since these substances produced changes in some of the other formed elements of the blood, it was possible that the increased uptake of lymphocytes by marrow might in some way be related to these changes.

understanding of structure could often only be gained through also studying function

HONORARY DEGREES

The university convocation which followed, Lord In received the honorary degree of DCL, and the Orator, who presented him for the degree, drew attention to the felicitous results of the combination of education in subjects of practical importance "with experience in the management of great affairs," as exhibited in the career of the Lord Privy Seal. In addition, Prof G W Corner, of Baltimore, Prof M W Siedman, of Amsterdam, and Dr L S B Leakey, Nairobi, received the honorary degree of DSC. The President gracefully disclaimed any detailed knowledge of the contents of Professor Corner's embryological papers, managed, as in his other orations, to find a singularly apt quotation to apply to the occasion. Professor Siedman's work on experimental embryology was mentioned as well as his distinguished war record, and attention was made of the practical skill of Dr Leakey as an anthropologist and palaeontologist.

SCIENTIFIC CONTRIBUTIONS

In the afternoon the congress settled down to the scientific business. Since there were over 200 communications and 90 demonstrations, as well as a number of films, it is clearly impossible to mention individual contributions except by way of illustration. In his opening address the President had spoken of the wide range of modern anatomy, and nothing could underline this point more effectively than a study of the subjects of the communications and demonstrations. These ranged from the mode of recovery of vision in transplanted salamander eyes (L S STONE) to the use of radioactive phosphorus in the study of the growth of bone and teeth (L F BELANDER and C P LEBLOND).

From a radiographic study of the mechanism of swallowing (F H KEMP) to the recovery of sensibility in skin grafts (J R NAPIER and R E M BOWDFIN) in fact, to someone unacquainted with the way in which the face of anatomy has changed in the present century, and the rapidity with which it is still changing, might seem startling that some of the communications were under the heading of anatomy at all. For example, there were papers on the effect of ultrasonic vibration on the albumin molecules in blood (W BEJDL), on the rate of spread of the virus of mouse encephalomyelitis (K SANDERS) on the velocity of blood flow in the glomeruli (J F HEGGIE) and on the changes in electroencephalogram produced by destruction of the hypothalamus (W R INGRAM et al). These and many other papers showing a similar diversity of interests illustrate the variety of techniques which can be made to serve the ends of modern anatomy, and the wide range of anatomy on other related subjects. The "overlap zone" where one subject meets another is in the most productive of new advances and the intimate nature of anatomy ensures that it is involved in a great number of these overlap zones.

The communications and the demonstrations were grouped under several broad and often elastic headings, and, both, the greatest number of entries came under the heading of neurology. The nervous system is to the anatomist what the Amazon basin is to the geographer—of the great remaining unmapped areas—and it was from the work reported at the congress that the work of constructing maps was in very active progress. In the histology section there were several papers on the use of phase-contrast microscopy, and one whole session was devoted to papers dealing with bone. Among the communications under the heading of general anatomy one advocating the extensive use of films in the teaching of anatomy (H KUH) An informal discussion

on this topic led to the congress resolving to form an international committee to collect and collate information on existing anatomical films from all the sources possessing such films, with a view to the production of a catalogue. The resolution envisaged the possibility of forming an international lending library of anatomical teaching films.

Embryology and morphogenesis included, as might be expected, many interesting papers, as did the section on endocrinology, in which several investigations on the structure and function of the pituitary were reported. The section on physical anthropology produced a stimulating discussion on the relationships of the Australopithecine, thanks to the discoveries of Dr Broom, Dr Leakey, and others, Africa is now the continent in the forefront of anthropological interest.

Finally a discussion was held on the vexed question of progress towards a uniform international anatomical terminology. It was agreed that the President should invite the various national anatomical societies to appoint delegates to a committee to consider how best the great B.N.A. terminology might be modified to meet the present-day demands of workers in anatomy and in other fields. It was also agreed that this committee should have a paid secretary, and it was suggested that an approach should be made to Unesco for this purpose.

SIDE SHOWS

Throughout the congress every opportunity was given to the assembled anatomists to have a very pleasant stay in Oxford, and there were many excursions and other entertainments available, including a dance at Oriel College. In the Radcliffe Science Library a fascinating exhibition was on view, showing the history of the teaching of anatomy at Oxford, and among the programmes and literature handed to the visitors on their arrival was a booklet, prepared by Dr H M Sinclair and Dr A H T Robb Smith, which gave an authoritative and extremely interesting account of this subject.

As is nearly always the case, the feature of the congress which was most appreciated by the delegates was the opportunity afforded of meeting each other informally and of exchanging "off the record" views and speculations. This opportunity was the more valued on this occasion because of the previous infrequency of such meetings and the time which had elapsed since the last one.

FINAL SESSION

At the concluding plenary session, held on the Friday afternoon, Professor LE GROS CLARK bade a formal farewell to the members. In a short speech he made reference to the tragic death of Prof H C Bazett on his way to attend the congress. Prof J BENOIT, for the French anatomists, Prof N L HOERR of the United States, and Prof CAULLERY of the French Académie des Sciences all expressed, on behalf of the delegates, their appreciation of the organisation of the congress which had contributed to its success. Professor Caullery referred to the threat to science and to the world of the present international situation, and hoped that this threat would have been dissipated by the time of the next congress. Professor Benoit proposed that this congress—the sixth—should be held in Algiers in 1955, and extended on behalf of the Association des Anatomistes de Langue Française a very warm invitation to the delegates of the present congress to attend it. At the same time Professor Hoerr, on behalf of the American Association of Anatomists, issued what he termed a "standing invitation" to anatomists to hold a congress—perhaps the seventh—in the United States. Both these invitations were enthusiastically received, and the congress broke up in the happy expectation of repeating a most interesting and stimulating experience in the not too distant future.

S WEINTRAUB and his associates (New York) gave teropterin in 102 cases of metastatic malignancy and concluded that, although no objective signs of improvement occurred, the subjective improvement (relief of pain, sense of well being, and improved morale) noted in 55% of these cases indicated that teropterin was a valuable palliative for incurable cancer.

G H TWOMBLY (New York) described the preparation and properties of C^{14} labelled stilbœstrol, although only animal experiments were performed, this substance may be of value in studies of œstrogen metabolism in malignant disease in man.

DIAGNOSIS AND TREATMENT

G E MOORE (Minneapolis) discussed the localisation and diagnosis of brain tumours after intravenous injection of fluorescein dyes. The dye concentrates in the tumour, and tumour tissue is easily identified by fluorescence in ultraviolet light. Preoperative localisation of brain tumours was accomplished by injecting radioactive fluorescein dyes intravenously and surveying symmetrical areas of the head with a shielded Geiger Muller counter. B SILVERSTONE, W H SWIFT, and C V ROBINSON (Boston) used intravenous injection of P^{32} for localisation of brain tumours, a special Geiger Muller probe counter was used for detecting tumours below the surface of the cortex.

S A GLADSTONE (New York) described the technique and value (e.g., in ulcers of palate, gum, and cheek, carcinoma of cervix, carcinoma of rectum) of "sponge biopsy." A sponge of gelatin or cellulose was rubbed over the ulcer or mucous membrane, fixed in 10% formalin, and taken through to paraffin, the stained sections were then examined microscopically.

A ALY (Cairo) reported good results in the treatment of 7 chromophobe pituitary adenomas after radium treatment by the intranasal route.

T WIKLUND (Stockholm), and A OCHSNER (New Orleans) described their experience of bronchogenic carcinoma. OCHSNER stressed the importance of palliative resections, not only to relieve symptoms of infection and obstruction but actually to prolong life.

R W RAVEN (London) and G T PACK and T R MILLER (New York) described the importance of radical surgery in the treatment of malignant melanoma of the skin.

H R BIERMAN and his colleagues (San Francisco) described a technique for catheterisation of the aorta,

cœliac axis, superior mesenteric, and renal and demonstrated some remarkable arteriograms. A cannula was introduced through the brachial, and was followed by fluoroscopy. The technique primarily designed for the intra arterial injection of nitrogen mustard into arteries directly.

EXPERIMENTAL PATHOLOGY

H M EVANS and his colleagues (Berkeley) described tumours (lung lymphosarcomas, adrenal pheochromocytomas, mammary fibroadenomas, ovarian tumours) in adult female rats after 10 injections, over long periods, of large amounts of pituitary growth hormone. V KORENCHEVSKIY (Leningrad) found adenomas or adenoma like structures in thyroid, parathyroid, adrenals, pancreas, and liver in adult rats treated with anterior pituitary sex hormones (e.g., testosterone), thyroid or deoxycortone. Every organ in the adult rat contains nests or foci of hyperplastic and metastatic cells, tumours could arise spontaneously by stimulation by hormones of the growth of such cells, or, as in these experiments, by artificial hormone stimulation.

H L STEWART (Bethesda) reported the results of intramural injection of methylcholanthrene into different sites in the glandular stomach of the rat. The pyloric region was 3-4 times more sensitive to the development of tumours than the fundus.

P R PEACOCK (Glasgow) reported that fowls bearing Rous sarcomas, and cauterised at sites remote from the tumour, localised the tumour in the cauterised area within 7-10 days. Application of the cautery before the development of the tumour did not localise the infective agent. No similar localisation was observed in birds bearing chemically induced tumours or grafts from such tumours.

C HOCH LIGETI and D S RUSSELL (London) described the development of primary brain tumours in rats fed 2 acetylaminofluorene. Tumour production was not prevented by a fresh milk supplement although the size of the tumours and the longevity of the rats seemed to be influenced.

H A SISSONS (London) observed bone sarcomas in rabbits after intravenous injection of beryllium compounds of low solubility. These tumours were remarkably like human osteogenic sarcomas and they metastasised to lymph nodes and to the lungs.

INTERNATIONAL ANATOMICAL CONGRESS

INTERNATIONAL congresses in most medical subjects are now familiar events, and it is perhaps strange that an International Anatomical Congress should still be a comparative rarity. Until this year there had been only four such congresses, none of them in this country. The last of these took place in Milan in 1936, so a considerable time has elapsed since the previous international meeting of anatomists. Last week, however, this gap was bridged when an International Anatomical Congress was held at Oxford from July 25 to 28, under the presidency of Prof W E LE GROS CLARK, F.R.S. It is in keeping with the general trend of such meetings that there were more members than in any of the previous congresses—over 550 attended, from 36 different countries. The largest overseas delegation came from the United States, and of the European countries most members were provided by France, Italy, and Scandinavia. The only Eastern European country to be represented was Yugoslavia, with three participants.

Before the congress itself began, all the members were entertained at a Government reception held in Christ Church on the night of July 24. The guests were welcomed on behalf of the Government by Viscount

ADDISON, K.G., F.R.C.S.—himself at one time a distinguished anatomist.

PRESIDENTIAL ADDRESS

At the opening plenary session the next morning, President, after welcoming the delegates, went on to review the progress which had taken place in all fields of anatomy during the last decade, illustrating his review by reference to the papers on the agenda for the congress. He emphasised the steady breaking down of the artificial barrier between anatomy and physiology. Anatomists were now becoming more physiologically minded, and physiologists more anatomically minded, which represented a return to the attitude of some of the older anatomists, such as Harvey and Hunter. Prof. Le Gros Clark went on to emphasise the value of the experimental approach in elucidating problems such as those of neuroanatomy and, on the other hand, the necessity for a continual extension of the field of topographical detail owing to the progressive encroachment of surgery on areas of the body which until recently were deemed to be the surgeon's. He concluded that the primary business of the anatomist was with structure, but the

there are no figures to prove these mass examinations on a national scale justify the energy and expenses involved."

Exhibition

scientific exhibition was a model of its kind, where were assembled on the one hand sets of radio sets exhibiting unusual features of medical interest, and on the other the working tools of the hospital physicist. Once the radiological mode of treatment is decided, then comes the planning by the physicist of the distribution of the radiation and the means to be adopted for measuring the dose delivered either to a particular part of interest or what is termed the integral dose. These matters are now carried through with a fine degree of exactitude, and it is an index of the individual work of the physicists that so many have designed their own dose meters. This has been going on for a good many years now, for the attractive historical museum, where the hand of the museum expert was prominent, contained the earliest model (about 1910) of an X-ray quantummeter.

In adding a final word about the Technical Exhibition which occupied the whole available space on the ground floor of the two halls of the Royal Horticultural Society, it is difficult to avoid the use of the superlative. Certainly there has never been staged in this country an exhibit of radiological equipment so complete or satisfying. The highest quality of design and workmanship was evident here, and there were exhibits from France, Italy, Germany, Holland, the U.S.A. as well as a very considerable home quota. The needs of diagnosis and treatment are being studied to the very last detail.

* * *

The next international congress of this kind is to be held five years hence in Copenhagen. It is on the records that the present one has entailed two years' work on the part of the president, Dr. Ralston Paterson, and his colleagues. It is no empty phrase to say that the radiological world will long be indebted to them all for the truly wonderful way in which the work of this congress was planned and carried out.

Special Articles

DISTRIBUTION OF

GENERAL PRACTITIONERS

THE Medical Practices Committee has completed its survey of England and Wales as at Jan. 1, 1950. As in the first survey, published a year ago,¹ all executive medical areas or parts of them have been assigned to four categories, two of which (I and IV) we print below. Any application to practise in areas named in schedule I will be granted "forthwith." Schedule II contains the names of other areas where applications will be granted automatically. The names of doubtful areas, where factors are not specifically needed, are given in schedule III, and here each application must be carefully considered "in the light of the position at the time." Schedule IV names the closed areas where the number of practitioners is considered to be adequate.

Schedule I

COUNTIES

Cheshire—Runcorn district (with the exception of Frodsham and Helsby) Crewe (Crewe and Nantwich district) Haslingham and Nantwich district.
Derbyshire—Ilkeston B.; Alfreton Clay Cross Heanor Longton, Ripley Swadlowclough U.D.s Blackwell Chesterfield R.D.s.
Durham—Hartlepool B. Jarrow B. Blythdon. Felling, Blaydon Ryton Whickham U.D.s, Bishop Auckland Crook and Blington, Shildon Spennymoor Tow Law Boldon Hetton Leazes Spring Seaham U.D.s Easington, Sunderland R.D.s.

INTERNATIONAL CONGRESS OF RADIOLOGY

As described in our last issue, this congress opened in London on July 24 under the presidency of Dr RALSTON PATERSON. There were 2700 delegates and the meetings included no fewer than 20 symposia with 108 contributors. In addition, over 300 proffered papers were with few exceptions read by their authors.

Symposia

The two subjects of radiodiagnosis and radiotherapy claimed the greater part of the programme, but there were large audiences for such symposia as Acceleration of Particles and Generation of Ionising Radiations. Here the contributions gave the impression that technical ingenuity in the raising of electrical potentials is well ahead of therapeutic demand, whereas after hearing about the latest advances in Angiocardiography it seemed that exacting radiographic demands were not yet being fully met. Supervoltage Radiotherapy claimed a session, and here a sober and cautionary note was struck, the technical difficulties faded into the background compared with the anxieties of the therapist as to what is going on beneath the skin of the patient. Deep seated damage has now taken the place of the previous skin reactions to stay the hand in pushing the dose, the fact is that the reaction of the skin with supervoltage radiation can no longer serve as a reliable guide to the patient's reaction. Modern skill has perfected rotational beam therapy either by rotation of the X ray beam or by rotation of the patient's table, so that with heavy doses at a depth the skin receives doses that it can well tolerate. The day has come therefore when the skin reaction cannot be a guide to the therapist during the long process of delivering a lethal dose to a deep seated malignant growth. Can he look in any other direction for this?

A symposium on Radiation Histology included three references to prognosis in radiation treatment. One was a direct negative to the question whether a prognosis of value can be given solely on the histological type of a malignant tumour. Secondly, comment was made on the method of histological study by means of biopsies taken at intervals during treatment: the degree of success so far attained by this method may be found in the Medical Research Council's report of *Researches on the Radiotherapy of Oral Cancer*, which we reviewed last week (p. 179). From quite another point of view came a quantitative measure of the "degree and duration of effects" after irradiation.

Two normal constituents of the blood, antichymotrypsin and antitrepanin have been studied. In actively progressing cancer the former substance exceeds the latter quantitatively, and irradiation reverses this condition within a few days of treatment. A five to ten fold increase in serum antitrepanin, with coincident fall in antichymotrypsin is characteristic of a favourable response. It is obviously the work of some clinical laboratory to combine these two methods and see whether an unfailing guide to the therapist can result.

ACTION OF IONISING RADIATIONS

Exactly how the ionising radiations act upon living tissues was discussed or touched upon in no less than three separate symposia, and here chemists, physicists, biologists, and geneticists joined issue. The chemists made one suddenly aware of the gap between atomic and molecular studies, while the geneticists as a whole deplored the lack of certainty which lay at the very basis of their studies. What in fact do we know of the normal mutation rates for the normal cells of the body? There is little doubt that X rays and other ionising rays act by virtue of the ions set free in the tissues they enter, and that ionic concentration or ionic gradients

determine the degree and nature of the otherwise realised, but opinion may well range cytoplasm to the single gene within the in seeking the weakest link in the resistance of it to its own destruction.

PARTICULAR SITES

Three symposia were related to the treatment of specific sites of cancer—the larynx, breast, and As illustrating the surgical point of view as to how to treat cancer of the larynx, graphs were shown giving 92 replies to a questionnaire on this point. Group I (Broders) a large majority favoured whereas for group IV opinion was evenly divided between operative measures and irradiation. In the treatment of cancer of the breast it seems that needling method, largely replaced in this country external irradiation, is still used in at least one important Belgian centre. In uterine cancer the best results still obtained in cases of the cervix uteri, and it is of great interest here to see how radiotherapists must be improving the already good results. Perhaps it may be true to say that the radiation treatment of no variety of malignant disease has been the subject of a sustained and devoted study as that of the cervix uteri, and because of this the patient with this disease recognised and treated in stage I, has the expectation of a "five-year cure" loaded considerably in his favour.

RECENT ACHIEVEMENTS AND THE FUTURE

In the symposium on Radioactive Isotopes both diagnostic and therapeutic work was discussed. The predominating interest was diagnostic, for the tracer elements are being rapidly put through their paces to see which of them will best suit the varied needs of the physiologist and the microscopist as well as the medical radiologist. But in therapy radioactive iodine phosphorus are under test as therapeutic agents. world over, and not mainly in the field of cancer. In the symposium devoted to achievements since 1945 the chief landmarks in diagnosis and therapy were outlined and occasionally a deficiency noted, as for instance the lack of any reliable method of detecting early carcinoma of the stomach.

The growth of organised therapeutic methods suitable for countries with such a population as ours proved a matter of great general interest.

With nearly all radiological practice there is a degree of irradiation of personnel. The impetus given during the war to obviating radiation hazards connected with the handling of relatively enormous quantities of radioactive material used in atomic energy projects in the U.S.A. has somehow been carried along into radiological work everywhere. There is in fact need for the closest attention to the dangers from the penetration of radiations, and this need is likely to increase as years go on. The warnings of the geneticists that mutations induced by radiation are recessive in character cannot be disregarded. There is, however, no need to think of the nation as in danger on this account, nor is it necessary to question the propriety of carrying out mass radiography of large numbers of people because of the possibility that these brief exposures could harm them.

Whether mass radiography will continue to be on an increasing scale depends on other factors. Its value, is self-evident, but its justification has to be determined on general economic grounds. One speaker at the symposium on this subject went so far as to

TREATMENT AND RESULTS

of tuberculous meningitis rarely responded to intramuscular injections alone, and still rarely when miliary tuberculosis was present. Local treatment gave appreciably poorer results applied on 50% or less of the intramuscular days in a given period than when applied intensively. "The general trend of results within encephalic clinical groups seems to be towards better rates of survival with more intensive intrathecal treatment. This assumes, however, concurrent intrathecal treatment for at least two thirds of the days in the period." But "there is no unequivocal evidence of optimum level of intensity of intrathecal treatment 75% of the days in a given period."

Cases of miliary tuberculosis without meningitis, s.f. should be examined at the start of, and at intervals during, streptomycin treatment. One third of cases of miliary tuberculosis so treated developed meningitis during treatment, and about one fifth died of it. There was no evidence that "prophylactic" local treatment prevented meningitis in such

Assessment of Results—As regards the C.S.F. the standard which was adopted for "normality" was white cells not more than 4 per cmm, protein not more than 40 mg per 100 ml and sugar not less than 40 mg per 100 ml. During the period of observation there was no instance of relapse in a patient whose C.S.F. had attained that standard, being at the same time clinically fit and well.

Laboratory Findings—The report observes that in the absence of bacteriological proof of the diagnosis, a large number of "negatives" may precede a positive result. Over a period of 10 months, one patient had 61 negative results before a positive was obtained.

Parliament

Last Stages of the Medical Bill

WHEN this Bill was considered on report in the House of Commons on July 21, Mr ARTHUR BLINKINSOP, Parliamentary Secretary to the Ministry of Health, introduced a new clause empowering the G.M.C., for those suffering from disability, to substitute an equivalent in medicine for the prescribed period of practice in surgery and midwifery. The clause was added to the Bill.

In clause 14 Mr Blinkinsop moved an amendment to ensure that, among the 9 members who would normally be invited to attend the medical disciplinary committee of the G.M.C., at least 2 would be elected members of the House of Commons. The amendment was agreed to.

In clause 15 Mr Blinkinsop moved an amendment to give statutory form to the present penal cases committee of the G.M.C. and to secure that there should be no overlapping of membership of this committee and medical disciplinary committee. The amendment was agreed to.

Mr HUGH LUCAS-TOOTH recalled that in committee there had been some discussion on an amendment introduced by Dr Hill in which it was suggested that a permanent department be set up to make a complaint to the G.M.C. should institute some preliminary investigation, and that the complaint should be fortified by the statement of an officer of the department. Sir H. Hill then moved an amendment of more moderate character, but on similar lines, which proposed that such a matter was referred to the Council for consideration. It should be set down in writing and that some responsible person should take responsibility for the amendment on which the complaint was founded.

Mr ANEUBIN BEVAN said there was an agreement between the G.M.C. in 1932, after formal consultation with

representatives of the Insurance Acts Committee of the B.M.A. Under this agreement particulars of disciplinary cases investigated by executive councils (at that time the insurance committees) were set before the G.M.C. when they related to cases of irregular or lax certification, to cases of unprofessional conduct, to cases in which allegations of canvassing or fraud were established or substantially supported, since 1914 to cases involving professional negligence. Copies of the following documents were sent to the G.M.C.: the report of the medical service committee or the local medical committee in certification cases of the executive council, the decision of the executive committee on the report, the report of the persons who heard any appeal against the decisions of the council, the representations, if any, made by the practitioner to the Minister on the question whether any money should be withheld from his remuneration, the letter of the department conveying the decision of the Minister, the report of the tribunal in cases where the tribunal decided to remove the practitioner from the list. Mr Bevan said that all these documents were either signed or approved by persons or bodies. It was not practicable for the department to endorse the facts therein stated which were not within their direct knowledge. If the practitioner contested for instance, the facts in the report of the general medical service committee, his remedy was to appeal and the report on the appeal would set out his case. The amendment was by leave withdrawn.

On clause 17 which deals with amendments as to striking off the register, Mr Bevan moved an amendment to meet points raised on the Committee stage, which he described as so muzzling the blade as to make it almost look like a benediction. The removal of cases by the G.M.C. was avoided but while the facts were taken as facts, a form of language was used that did not load the name of the individual concerned with what Colonel Elliot had called "a penumbra of guilt or a nimbus of turpitude." The amendment was agreed to.

On clause 33 Mr Bevan moved an amendment providing that no order prescribing the length of the intern period should have effect unless a draft had been approved by resolution of each House of Parliament. The amendment was agreed to.

The Bill was read the third time and passed with amendments.

In the House of Lords on July 26 the Commons amendments to this Bill were agreed to, and on July 28 the Bill received the Royal Assent.

QUESTION TIME

Shortage of R.A.M.C. Officers

Major NIAL MACPHERSON asked the Secretary of State for War what was the present deficiency of regular commissioned specialists in all branches of medicine and surgery, on the basis of existing establishment of the Royal Army Medical Corps, to what extent the deficiency was being made up by civilian specialists and what steps he was taking to overcome the shortage of regular specialists at an early date, and what was the present deficiency of permanent and short service regular qualified doctors in the R.A.M.C. on the basis of present establishment and what was the total deficiency after taking into account National Service doctors, and what steps he was taking to overcome the shortage.—Mr JOHN STRACHEY replied. The deficiency of regular including regular short service doctors is 381. This figure includes 13 specialists. Taking into account National Service doctors the total deficiency is 265 which includes 115 specialists. With a view to overcoming these shortages, an examination of the rates of pay of doctors and specialists is being carried out, 66 civilian medical practitioners and 10 civilian specialists have been employed and 49 medical officers including 12 specialists, have been given type "B" commissions for one or two years or have been granted special deferments. Conditions for short-service commissions for women doctors will shortly be promulgated and proposals are now under discussion for reopening short-service commissions for specialists which are calculated to attract highly qualified doctors from civil life.

Major MACPHERSON asked the Minister whether he would now bring the emoluments of qualified doctors and specialists

Durham—Gainford Middleton in Teesdale (Barnard Castle R D), Sedgfield Village and Stillington (Sedgfield R D)

STREPTOMYCIN IN TUBERCULOUS MENINGITIS

MINISTRY REPORT

THE Ministry of Health organised through the medical schools in England and Wales, and with the cooperation of certain hospitals in Northern Ireland, an investigation into the efficacy of streptomycin treatment of tuberculous meningitis. The Ministry has now issued an analysis of the results.

The report covers 369 bacteriologically proven cases of tuberculous meningitis, with or without generalised tuberculous, which were observed for 10 months. The mortality for the whole series was 74% and for early cases 50.7%. Of those who survived, 31% had normal cerebrospinal fluid (C.S.F.) and approximately 89% were clinically fit and well. "It appears to be a belief prevalent amongst many medical practitioners that streptomycin treatment does no more than prolong life or produce 'recovery' as a physical and mental wreck. This is not true." Of patients treated early in the disease, some 40% "made a complete recovery except in some instances for minor disabilities which at the time of assessment did not interfere with their leading a normal life."

The 104 survivors were followed up at the end of the further year, giving observation periods varying from 22 to 33 months. All were still alive, 88 were clinically fit and well, and 59 (57%) had normal C.S.F. Of the 16 not fit and well, 6 were under 4 years of age and were described as "mentally retarded", 2 were suffering from genito-urinary tuberculosis, and 8 who had been "unfit" at the assessment a year earlier compared with 3 with bone or joint tuberculosis, 1 with optic atrophy, 2 paralysed and incontinent, and 2 "emotionally unstable," one of these being also deaf. At the end of 22 months the over all survival percentage was 74% for meningitis alone, and 17 for meningitis complicated by generalised tuberculous. Among those observed for longer periods there was no fall in these percentages. For "early" cases there were 48% of survivors at 12 months and at 2½ years, but for "advanced" cases only 12% at 13 months and only 10% at 2½ years—differences which underline the importance of prompt treatment.

"With the general release of streptomycin to all practitioners and hospitals there has been a considerable decrease in the number of patients admitted for treatment to the selected hospitals participating in this investigation. In order that research may be carried out on the merits of different modes of employment of streptomycin in patients clinically comparable, adequate numbers are needed. It is most necessary therefore to give selected hospitals the opportunity for admitting patients if they have accommodation available."

Northern (42), Wales and North Western (39), and West Ridings (36), and Midland (33), and was in North Midland. The rates in the other regions (25), London and South Eastern (25), Southern (26), and Western (20)—were all less than the general

Among the towns with populations exceeding the following had the highest rates: Liverpool (44), upon Hull (41), and Coventry and Newcastle upon Tyne (39). The lowest rates were recorded in the big large towns: Harrow (20), Leicester (23), Portsmouth (24), London (27), and Croydon (28), while the urban borough of Lewisham had an exceptionally low rate of 19. The rate in Oslo was 20 and in Paris 48.

Survey of Sickness

the people interviewed about their health in the number quarter, 1949, 64.9% out of 8778 men and 10,847 women had suffered from illness or during October, November, or December. The ponding figures in the December quarter, 1948, 65.0% and 75.5%. The percentage of men who visited a doctor during a month was 41.5 and that of women 48.0, the latter figure having dropped from 47.0 a year earlier. The average number of days' incapacity in a month due to sickness was 1.12 among men and 1.30 among women. Housewives (65% of the men interviewed) consulted doctors to the same extent as other women. A higher proportion of them reported some illness or injury (77.0% per month), but reported less incapacity (1.15 days per month).

Deaths in 1948

In the medical tables volume of the Registrar General's Statistical Review for 1948¹ records that 468,645 persons died in England and Wales during that year, a decrease of 46,940 from the previous year's figure. This gave a crude death rate of 11.0 per 1000 civilian population, the lowest ever recorded in this country; the previous lowest rate was 11.4 in 1930, when the number of deaths was 455,427. Of the deaths, cancer accounted for 16.9%, compared with 15.1% in the previous year and 13.9% in 1938.

Coronary Disease—Deaths due to diseases of the coronary arteries and angina pectoris again showed a substantial increase numbering 30,640, compared with 33,168 in 1947, 28,010 in 1946, and 15,409 in 1938. Discounting the changes in sex and age structure of the population, the mortality from this cause has practically doubled over a period of years.

Cancer—Male mortality from this cause again increased in 1948, while female mortality showed a slight decrease in the two previous years. The decline in deaths from cancer of the mouth continued, but as noted in previous years, other affected sites showed increases. Cancer of the respiratory system showed increases for both sexes: 15 for men and 2158 for women, compared with 8603 in 1947 (representing just over half the total increase in cancer mortality).

Diphtheria—Deaths from diphtheria numbered 155 in 1948, a rise from 242 in 1947 and 2861 in 1938. This represents about 95% in mortality from this cause over the years (During 1949 only 85 deaths from this were recorded).

Road Deaths—There were 3859 (2809 male and 1050 female) deaths due to road accidents in 1948, compared with 4187 in 1947 and 7314 in 1939. Of the 3859 persons killed, 2041 (53%) were pedestrians, 722 (19%) were pedal cyclists and (8%) were motor-cyclists. Of the pedestrians and cyclists (total 2763), 694 (25%) were children under 15 years of age.

Deaths of Infants and Mothers—The infant mortality rate was 34 per 1000 related live births (compared with 41 in 1947 and 43 in 1946) and was the lowest recorded in this country up to that time. (The provisional rate for 1949 was 32 per 1000.) The maternal mortality rate was 0.86 per live and still births compared with 1.02 in 1947 and 1.14 in 1946, in 1938 the rate was 2.70.

In England Now

A Running Commentary by Peripatetic Correspondents

We have been having some sporadic cases of primary atypical pneumonia in this district, so when I was told that John, aged 5, had a persistent cough and had been feverish for five days, the scattered rales at both bases and high titre of cold agglutinins made me add him to the list. He seemed a fairly severe case and I felt that 'Aureomycin' was justified. The dosage schedule was laid down, but John insisted on being left alone to swallow each capsule as it became due. To the mother I confidently foretold improvement for the morrow and a change on the chart from jagged peaks to a steep and steady decline. And so it was. The curve flattened below the thick black line and remained there. His appetite improved. Mother and doctor congratulated each other on the wonders of modern science.

This morning all the capsules were found in a little pool of dried saliva at the bottom of the wardrobe. John isn't so well today. Neither he nor his doctor can look one another straight between the eyes.

* * *

I can still remember the surprise of a colleague of mine during our first year as medical students on learning that Anatomists cut up "real people," and there can be no doubt that merely because of their choice of a medium for self-expression, Anatomists tend to be regarded as a race apart. They live generally at the very top, or else at the very bottom, of large forbidding buildings and often surround their dissecting rooms with inscriptions in Latin or Greek designed to quell the ebullience of youth. In addition, they talk a strange Romish tongue. It often turns out, therefore, that to the sensitive student one Anatomist constitutes a crowd, and two, particularly under the noms de guerre of "internal" and "external," induce an insufferable sense of claustrophobia.

It may be that this feeling is to a certain extent shared by the Anatomists themselves, for in an age of International Congresses they have shown themselves singularly chary of congregating. Until this year, in fact, no International Anatomical Congress had been held on British soil. The congress at Oxford last week, however, demonstrated that, when put to it, Anatomists can Congregate with the best. Their consumption of morning coffee and afternoon tea—always the barometer of a successful congress—was well up to British Physiological standards which are among the highest in the world, and the mad lust for Excursions, which glows in the hearts of all true Congregators, leaped into flame in many Anatomical breasts, so that it was reported that at least one Anatomist found himself simultaneously in two buses proceeding in opposite directions. In short, Anatomists, like their raw material, are real people.

I sat in an inconspicuous seat to the right of the median plane, inferolateral to the lantern and two thirds of the way along a line joining the lecturer to the superior ventilation duct, with the hard bench inferior to my posterior. As far as the eye could reach in all directions around me were Anatomists. What would they discuss, these clear eyed men who had read through big Cunningham (and some of them even through Gray also)? "Some remarks on an anomalous contribution to the lesser superficial petrosal nerve in a pair of anencephalic heterozygous twins"? "Three cases of persistent reduplication of the intermediate layer of the suspensory ligament of Treitz, with some observations on the morphogenesis of the recurrent branches of the Batrachian sphenopalatine ganglion"? I sat back and prepared myself to allow the measured incomprehensible periods to flow over me. But Anatomy is not what it was, the subject matter catered for all comers, from the sophisticated interested in how his fingers and thumbs work down to the ingenuous clinician seeking information on the action of streptomycin or the mode of spread of virus diseases.

Surgeons and medical students often suppose—and often rather sourly—that the only reason why Anatomists get together is to authorise yet a further change in

serving on regular commissions in the R A M C into line with those applying under the National Health Service—Mr STRACHEY replied. The rates of pay of medical officers and specialists in the R A M C are now being examined. Account will be taken of the average earnings of doctors under the National Health scheme.

Civilian Specialists

Major MACPHERSON asked the Minister what was the present scale of pay and allowances offered to specialists attached to the R A M C in a civilian capacity, for home and overseas service respectively—Mr STRACHEY replied. Civilian specialists serving at home are paid £1300 or £1600 a year according to experience and qualifications. Abroad they are paid £1800 or £2200 a year and receive an outfit allowance and a local allowance varying from £25 to £425 a year according to the station and whether they are married or single. These allowances are common to all civil servants of comparable grades. Free single accommodation and, in certain stations, free messing are also provided.

Hospital Administrative Staffs

Replying to a question, Mr A BEVAN said that detailed hospital surveys to determine what should be a reasonable ratio of administrative to medical staff and to patients, as a guide to hospital boards and committees, were about to begin.

Beds for the Tuberculous

Mr A E MARPLES asked the Minister how many beds suitable for tuberculous patients were empty, and how many could be used if there were staff available—Mr BEVAN replied. Hospital returns at Dec 31 last showed that approximately 5000 such beds were unoccupied on that date, of which about 4000 stood closed for lack of staff.

Replying to questions suggesting that further facilities should be afforded for the treatment of tuberculosis cases in Switzerland, Mr BEVAN said. I cannot undertake in present circumstances to add to the cost of the health service as proposed, but I have recommended to hospital authorities action for making the best use of our own resources.

Reduction of Extraction-rate of Flour

In answer to questions, Mr MAURICE WEBB, Minister of Food, said it had been decided to reduce to 80% the extraction rate of flour used for the national loaf. This would be made up of home milled national flour with a rate of 81%, and a proportion of imported flour with a lower rate. The change, which would take effect on Aug 27, would enable the public to get a whiter and more generally acceptable loaf while still meeting the standards recommended by the Post war Loaf Conference. It would also add to the quality and quantity of our supplies of animal feeding stuffs.

Dr BARNETT STROSS. Is the Minister aware that the 85% extraction rate, together with the high consumption of liquid milk, was responsible in the main for the continuously improving conditions in the health of the nation and will he tell the House that he does not contemplate any further degradation of that standard? Mr WEBB. This is our decision, and on it we stand. We have decided that it was possible to reduce the extraction rate at this point because of the high nutritional value of the extra amounts of other kinds of food which we are now able to supply.

Dr STROSS asked the Minister what was the iron content of wheaten flour at the rates of extraction 85%, 80%, and 72%—Mr WEBB replied. This depends on the grists (that is, the mixtures of wheat). But typical figures for 85%, 80% and 72% extraction rates are 2.1, 1.65, and 1.25 mg per 100 g of flour.

Tuberculosis in Scotland

Mrs JEAN MANN asked the Secretary of State for Scotland what consideration he had given to the report of the Scottish Committee on Tuberculosis Service in Scotland and if he would make a statement on the recommendation of crisis expansion of tuberculosis service—Miss MARGARET HERBISON replied. With his officers the Secretary of State has been studying carefully this report but has found in it no recommendation for the expansion of facilities which has not already been considered whilst most of the recommendations have been tried with varying degrees of success. In the last two years more than 300 additional beds have been

brought into use for respiratory tuberculosis, many in infectious diseases and general hospitals. The my right hon friend proposes to continue especially hospitals where nursing staffs are strongest.

Cruelty to Children

In the House of Commons on July 20 Mr CARMICHAEL, Home Secretary, in a statement on the report of a Government working party, which was appointed to inquire into cruelty and neglect of children in their homes, said. The Government had reached the conclusion that the need was not for an extension of statutory powers, but for a more co-ordinated use of the local authority and other voluntary services available. Local authorities had wide powers to assist families, and health visitors, school attendance officers, and others in regular contact with children were in a position to assist in bringing to light neglect or ill treatment. In addition, voluntary organisations, in particular the National Society for the Prevention of Cruelty to Children and the Royal Society for the Prevention of Cruelty to Children, were engaged in work in this field. The co-ordination of local statutory and voluntary effort could not be used to the best advantage unless there was effective co-ordination. It was of the first importance that help should be given at an early stage, and that the service which could be of most use before valuable time had been lost and harm had been done. If the right help was not given in time, children who otherwise have remained with their parents might have been removed from home because deterioration had gone too far.

The Government, he continued, had accordingly decided that the right course was to ask local authorities to make arrangements designed to ensure that action was taken to make the most effective use of the available resources of statutory and voluntary alike. The councils of counties, county boroughs (in Scotland, the councils of counties and large burghs) were being asked to make suitable arrangements to secure co-ordination among all the local services, statutory and voluntary, which were concerned with the welfare of children in their own homes. This might well be achieved by designating an officer of the local authority whose duty would be to ensure such co-ordination. By this means significant cases of child neglect and all cases of ill treatment coming to the notice of any statutory or voluntary organisation in the area could be considered, and agreement reached as to how the local services could best be applied to meet the need. The Government were convinced that it was on these lines that the problem could best be tackled and confident that local authorities and voluntary organisations concerned could be relied upon to co-operate freely in putting the arrangements into effect.

Food-poisoning

Replying to a question, Mr BEVAN stated that 63% of food poisoning had been notified to medical officers of health in the twelve months to March 31, 1950.

Public Health

Poliomyelitis

In England and Wales notifications of poliomyelitis for the week ended July 22 numbered 152 paralytic cases (152), non-paralytic 71 (80), total 223 (212). The total increase of 48 on the figures for the previous week (shown in parentheses) London contributed 20, Warwick 5, Stafford and Essex each 3, and Worcester 2. Four counties contributed 40% of total notifications. Warwick had 43 cases, London 24, Lancashire 24, and Stafford 24. Thus there is no evidence of any considerable spread to fresh areas.

Infant Mortality in 1949

Last year the rates of infant deaths in various parts of the country showed wide differences. For example the England and Wales over-all rate of 32 per 1000 related live births was exceeded in the following areas:

1 The Registrar-General's March Quarterly Return, No. 40, Stationery Office, Pp 36-12.

out his life Gosset stood for simplicity and He disliked formulae, and I am sure he would have disapproved of little books purporting to teach in a couple of hours. He would never have said so elaborate, but he seemed to feel that the of not carrying any argument back to first as far outweighed the little time saved. Is medicine so impermeable to these simple ideas, is it commonplace in almost every sphere of common production where bankruptcy weeds out the best? Is it because there is no bankruptcy and the price of a departmental chief rises as his department becomes more expensive? Or is it because no neutral chief can run ahead of the public opinion institution which he serves? Clinical pathologists have a unique opportunity to educate medical men in the meaning of the $\pm$ sign after a measurement. Commercial laboratory statistics are practised, not by the most junior lab boy learns in a few days to bandy standard errors. To return to the matter. Does any hematologist who knows the history, the hemoglobin, and the hematocrit, and who has a stained blood film in front of him, or further aid in diagnosis from a red blood cell which is likely to be more than 10% out in a third case, and more than 20% out in 1 in 20 cases? Have patients derived any benefit from these counts, or millions of hours during the last thirty years been wasted on boring work just because doctors are hoodwinked at arithmetic?

London Hospital, E 1

DENYS JENNINGS

—Since I wrote the above, Dr Campbell's letter of 29 has illustrated an important point. A patient's successive counts with a colour index of 1.06-1.11 show a variability of 2.5% instead of the expected 11%. As tests to which his figures can be submitted must show that they are "improbably" good. Dr Campbell has selected this case and that could be the basis of a nation. Analysis of blood-counts from different laboratories, however, suggests that most good technicians are "improbably" good. Consciously or unconsciously, they maintain a consistency in the colour index, which is almost certainly impossible. Dr Campbell's explanation is not acceptable. Like most contributors to medical literature he confuses two entirely different statistical arguments. If a patient's blood count is 3 million red cells and if there is no more likely figure which a good technician will give is 3 million, and a count of 2 million or of 4 million, is equally likely. But that is not the problem which confronts the practice when the technician tells us that the count is 3 million and we want to know what the most likely figure is. The answer to the practical problem depends on the type of case referred to the laboratory. In a bad case where 25 times as many patients with counts of 3 million are referred as patients with 3 million the chance of a patient with 4 million being misdiagnosed as under 3 million is about the same as the 1 in 2 chance of the patient who really has 3 million. In other words, when the laboratory returns the red-cell count as $3,000,000 \pm 400,000$, the most likely count may be 3,700,000. The paradoxical situation thus arises that the reference of normal patients to a laboratory diminishes the reliability of its reports. Dr Brailsford pointed out in non-mathematical language that the consideration applies to X-ray reports.

ACTION OF ASPIRIN ON THE COLON

—When I first had a "temporary" sigmoidectomy seven years ago, for rectal stricture following diverticulitis I had vague hopes of rivaling Pavlov, Wolff and Wolff by observing its behaviour. Alas, from a few practical details, I have learnt nothing worth recording, with one possible exception—action to aspirin.

Usually my morning washouts work like a series of enemata, I pump in a pint or two of water with my Higginson until, with a visible contraction of the protruding bowel, the whole lot, with fecal additions, is rapidly and violently returned. But occasionally these explosive contractions do not occur, instead, after 2-3 pints has gone in, the water begins to well gently out again, and the bowel can only be emptied by pommeling the abdomen and doing trunk-bending sideways exercises.

When this had happened several times I noticed that it followed a dose of aspirin overnight. Since then I have become fairly certain that gr 10 of aspirin stops my colon contracting normally when distended twelve hours or so later. And the effect is the same whether the aspirin has been taken for lumbago or toothache or for the more usual headache.

ORION

SURGICAL OPERATION AS TECHNICAL ASSAULT

SIR,—In view of the report in your issue of June 24 (p. 1168), it has been thought desirable to remind practitioners of the need to obtain proper consents in writing from patients or their relatives when the procedure recommended involves operative treatment.

It would appear to be necessary to make it clear to patients and/or relatives alike that when a patient is admitted to hospital for operative treatment, the operation proposed will not be performed necessarily by any particular surgeon who may have seen the patient previously or under whose name he is admitted. The forms of consent given below are considered appropriate by the solicitors to the Medical Defence Union.

CONSENT BY PATIENT

To the Medical Staff and Committee of Management of the _____ Hospital.

I, _____ of _____ hereby consent to undergo the operation of _____ the effect and nature of which has been explained to me.

I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anaesthetic for the purpose of the same.

I understand that an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this _____ day of _____ (Signed) _____

CONSENT BY RELATIVE

I, _____ of _____ the _____ of the above named _____ hereby also consent to such operation.

Dated this _____ day of _____ (Signed) _____

(The formula of consent by the spouse or near relative although not strictly necessary in law may save trouble afterwards.)

CONSENT FOR MINOR

To the Medical Staff and Committee of Management of the _____ Hospital.

I, _____ of _____ hereby consent to the submission of my child _____ to the operation of _____ the effect and nature of which has been explained to me.

I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anaesthetic for the purpose of the same.

I understand that an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this _____ day of _____ (Signed) _____

CONSENT FOR ELECTROCONVULSIVE THERAPY

To the Medical Staff and Committee of Management of the _____ Hospital.

I, _____ of _____ hereby consent to the administration of convulsive therapy the effect and nature of which has been explained to me. Notwithstanding the fact that there are certain risks of injury inherent in the treatment, I request you to administer the same to me and I accept any risk attaching to such administration.

I understand that an assurance has not been given that the treatment will be administered by a particular practitioner.

Dated this _____ day of _____ (Signed) _____

ROBERT FORBES
Secretary

Anatomical nomenclature Even these notoriously cynical men will be glad to hear that on this occasion the temptation was resisted, though there are sinister possibilities within the next few years I am also privileged to report that among themselves, and relieved of the necessity for putting a bold front on things before their students, Anatomists are just as prone as common clay to talk about the foramen of Winslow or the X-shaped ligament of Bigelow

Among the tintinnabulation of Anatomical shop in a multitude of foreign tongues and accents I could detect no syllable of Russian, apparently the Party Line on topography has not yet been established securely enough for a delegation to be permitted There were, however, plenty of dialectics and not a little materialism, which proved greatly to the taste of the assembled Congregators, while the Associate Members—who, as is well known, determine the success or failure of any congress—were at once soothed and stimulated by an atmosphere compounded of tea, sherry, Stratford on Avon, punting, and omnibuses In the result, the congress dispersed in an entirely satisfactory frame of mind to sharpen its scalpels and revise the relations of the radial nerve (or musculospiral) against the coming winter

* * *

The spoilt and well-provided neuter cat, ignoring his basket, spends his days luxuriating on a bed, a sofa, in an armchair, the airing cupboard, or that in which I keep my clothes All night he prowls about, preferably in the rain, catching field mice or half grown rabbits which he brings in and devours, fur and all, on the drawing-room carpet Why?

The elderly kitchen bitch, an ingratiating cupboard lover with a taste for maternity unassuaged by the passage of years, has recently nidified and brought forth six assorted pups in the hollow of a root, bang in the middle of the hedge behind the coal-shed, spurning the comfortable and convenient kennel provided by the management Why?

It would be hard to find any living thing more unaccountable than my domestic animals—except, of course, my patients

* * *

It is pleasant to record how much the delegates from 50 odd countries to the fifth International Cancer Congress, held in Paris, have enjoyed their experience of French hospitality The congress opened at the Sorbonne on "Dimanche, 16 Juillet, 1950, à 9 heures 30 très précises," and, though 9.30 A.M. on Dimanche is always a bit of a strain, the opening was well worth seeing A military band, 70-80 strong, occupied one side of the platform, and as the President of the Republic entered they played the *Marschaise*

As is almost inevitable at large congresses, some sections were (rarely) ahead of the time schedule and others were (frequently) well behind But the delegates were a benign crowd on the whole, and the only sign of malignancy was the rate of metastasis to restaurants and shows when the day's work ended The Grand Banquet and trips to Versailles and Reims were among the memorable social events

The Sorbonne was an ideal site for the congress Few of us newcomers will forget that grand old building and its warren of lecture-rooms Fortunately, these rooms were named and easily found, and soon one was rushing confidently from "Turgot" to "Michelet" or from "Richelieu" to "Guizot" The little lecture-theatre called "L Liard" is exquisite Behind the platform is a large painting of Richelieu, down the left side of the room there are oval portraits of Pascal, Bossuet, Descartes, and Racine, at the back we have Corneille and Molière, and yet another painting decorates the ceiling

* * *

The National Health Service has wrought changes in the correspondence we consultants receive, and it did not surprise me to be addressed as "Dear Madam" and asked to name the day for fitting the writer with a corset and "bra" But it was a bit of a shock to see on the envelope "To Doctor, Ministry of Corsetry, St X's Hospital"

Letters to the Editor

ACCURACY IN RED-CELL COUNTS

SIR,—Your leading article of July 15 would have greater force if a clearer distinction had been made between the different kinds of error

Successive samples differ from each other successive handfuls of coins contain different heads and tails The inevitable inconsistency repeated measurements depends on the size of the sample It is calculable, and it is distributed normally error which arises when a team of experts sample a reservoir of pooled blood is not calculable and is certainly not distributed normally it is distributed in the course of a series of observations, and it is dangerous to assume that it applies to other workers under different conditions The third type of error is the only one which concerns the practising consultant, and for some or other it is considered almost indecent to ignore it What is the actual error which occurs in practice which is increased by such imponderables as the patient being kept awake all night by his baby teething? There is no doubt that it is considerably larger than the theoretical error, but its distribution is sharply curtailed at the extreme by medical supervision, which leads to a stained film being examined when the colour and the "odd," and by "faking"

Let us take E_T , the total error, as 10-11% which is a low estimate $E_T = \sqrt{E_s^2 + E_e^2}$ where E_s is the working error and E_e is the theoretical sampling error If 500 cells are counted, E_s is just over 4%, and E_e is about 10% Automatic methods of counting which reduce the sampling error to a half will have an almost imperceptible effect on the total error

The work of W H Gosset ("Student"), whom I cited, deserves to be recalled When Gosset left N College and went into Guinness's in 1899 to devote himself to the clinical pathology of beer, commercial laboratories were as haphazard as modern hospitals Lack of statistical sense partially sterilised applied science made it too expensive Lack of the experimental look had endangered the reputation of statistics Combined both disciplines in an almost ideal way was ready as a statistician to state a research project in mathematical terms from first principles, and as an experimenter his enthusiasm was aroused when plausible theory proved false in practice Three of his principles should be heeded more closely in medicine Theoretical estimates of error tend to be too small, like other statistical deductions must be repeatedly checked in practice Estimates of error based on Tuesday's work in the laboratory are unlikely to be good for Fridays, when the staff is tired There is an ebb and flow of accuracy which follows the seasons as accident proneness

The second principle follows from the first Technique are not machines, and experience can create unexpected sensitiveness Budge Patty, at tennis and Bobby Locke, at golf, measure the strength of their shots with an accuracy which is almost incredible when we come to turn it into percentages Divided concentration is an enemy of this kind of accuracy The observer must put complete faith in his senses The possibility of conscious or unconscious cheating is a hundred times more likely than the error resulting from a knowledge of what the answer ought to be

The third principle derives from commerce Measurements and statistics cost money, and increasing accuracy means increasing expense Honest costing is an essential aid in deciding on the distribution of one's resources Elaborate measuring devices should not be preferred to the trained senses without giving both a fair

DENTS JENNINGS

—Since I wrote the above, Dr Campbell's letter ly 29 has illustrated an important point. A patient successive counts with a colour index of 1.06-1.11 a variability of 2.5% instead of the expected 11%. us tests to which his figures can be submitted est that they are "improbably" good. Dr pbell has selected this case and that could be the ination. Analysis of blood counts from different atories, however, suggests that most good tech- ns are "improbably" good. Consciously or nsciously, they maintain a consistency in the ur index, which is almost certainly impossible. Campbell's explanation is not acceptable. Like most tributors to medical literature he confuses two rely different statistical arguments. If a patient's blood count is 3 million red cells, and if there is no , the most likely figure which a good technician will h is 3 million, and a count of 2 million, or of 4 million, likely. But that is not the problem which confronts ractice when the technician tells us that the count llion and we want to know what the most likely is. The answer to the practical problem depends type of case referred to the laboratory. In a bad here 25 times as many patients with counts of on are referred as patients with 3 million, the 0 chance of a patient with 4 million being mis- d as under 3 million is about the same as the 1 in 2 of the patient who really has 3 million. In words, when the laboratory returns the red cell as $3\text{ million} \pm 400,000$, the most likely count may , 3,700,000. The paradoxical situation thus arises he reference of normal patients to a laboratory shes the reliability of its reports. Dr Brailsford nted out in non mathematical language that the onsideration applies to X ray reports.

ACTION OF ASPIRIN ON THE COLON

—When I first had a "temporary" sigmoid my seven years ago, for rectal stricture following ive colitis, I had vague hopes of rivaling Pavlov f and Wolff by observing its behaviour. Alas, rom a few practical details, I have learnt nothing worthy of record, with one possible exception— tion to aspirin.

Usually my morning washouts work like a series of enemas, I pump in a pint or two of water with my Higginson until, with a visible contraction of the protruding bowel, the whole lot, with fecal additions, is rapidly and violently returned. But occasionally these explosive contractions do not occur, instead, after 2-3 pints has gone in, the water begins to well gently out again, and the bowel can only be emptied by pommel- ing the abdomen and doing trunk bending sideways exercises.

When this had happened several times I noticed that it followed a dose of aspirin overnight. Since then I have become fairly certain that gr 10 of aspirin stops my colon contracting normally when distended twelve hours or so later. And the effect is the same whether the aspirin has been taken for lumbago or toothache or for the more usual headache.

ORION

SURGICAL OPERATION AS TECHNICAL ASSAULT

SIR,—In view of the report in your issue of June 24 (p 1168), it has been thought desirable to remind practi- tioners of the need to obtain proper consents in writing from patients or their relatives when the procedure recommended involves operative treatment.

It would appear to be necessary to make it clear to patients and/or relatives alike that when a patient is admitted to hospital for operative treatment, the opera- tion proposed will not be performed necessarily by any particular surgeon who may have seen the patient previously or under whose name he is admitted. The forms of consent given below are considered appropriate by the solicitors to the Medical Defence Union.

CONSENT BY PATIENT

To the Medical Staff and Committee of Management of the _____ Hospital

I _____ of _____ hereby consent to undergo the operation of _____ the effect and nature of which has been explained to me.

I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anæsthetic for the purpose of the same.

I understand an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this _____ day of _____ (Signed) _____

CONSENT BY RELATIVE

I _____ of _____ the _____ of the above named _____ hereby also consent to such operation.

Dated this _____ day of _____ (Signed) _____

(The formula of consent by the spouse or near relative, although not strictly necessary in law may save trouble afterwards.)

CONSENT FOR MINOR

To the Medical Staff and Committee of Management of the _____ Hospital

I _____ of _____ hereby consent to the submission of my child _____ to the operation of _____ the effect and nature of which has been explained to me.

I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anæsthetic for the purpose of the same.

I understand that an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this _____ day of _____ (Signed) _____

CONSENT FOR ELECTROCONVULSIVE THERAPY

To the Medical Staff and Committee of Management of the _____ Hospital

I _____ of _____ hereby consent to the administration of convulsive therapy the effect and nature of which has been explained to me. Notwith- standing the fact that there are certain risks of injury inherent in the treatment I request you to administer the same to me and I accept any risk attaching to such administration.

I understand that an assurance has not been given that the treatment will be administered by a particular practitioner.

Dated this _____ day of _____ (Signed) _____

LARYNGEAL VERTIGO

SIR,—The description of laryngeal vertigo in your leading article of July 15 is, no doubt, correct for the majority of cases. However, a prolonged bout of coughing is not necessary for the production of this syndrome, as can be seen from the following case report.

A man, aged 52, was recently seen in the outpatient department complaining of attacks of loss of consciousness. At the age of 35 he had developed asthma, to which he had since remained liable. His asthmatic attacks always began with a short bout of coughing. At the age of 48 he had developed his present complaint. He would begin a bout of coughing indistinguishable from those preceding his asthmatic attacks, but after the very first cough he would fall unconscious to the ground. Onlookers had told him that he was not convulsed, he was never incontinent, and recovered in a few seconds. These attacks were not followed by asthma.

He was not overweight, and the blood pressure was 140/80 mm Hg. There was moderate clubbing of the fingers and numerous expiratory rhonchi in the chest. There were no abnormal signs in the nervous system. Radiographs of the skull and chest were not helpful, and the electroencephalogram was within normal limits.

The immediate onset of unconsciousness following one short cough would appear to exclude cerebral anaemia as a cause in this patient. Similar cases can be found in the literature and in one of Charcot's cases¹ it was specifically stated that a short cough preceded the attacks, and that prolonged bouts had no such sequel. The theory of cerebral anaemia can scarcely be regarded as proven.

I am indebted to Dr F R Ferguson for permission to report this case.

Department of Neurology
Manchester Royal Infirmary

W B MATTHEWS

SIR,—About five years ago I had one attack of this dramatic complaint, it came on after dinner.

While talking I inhaled a mixture of tobacco smoke and steam from hot coffee, I remember a momentary catching of the breath but no struggle or suffocation, and unconsciousness was practically instantaneous. Perhaps a moment later consciousness gradually returned, but in another minute I was perfectly well, wondering what all the fuss was about. The really astonishing feature was the complete absence of struggle and the sudden total unconsciousness.

Six months after this experience, my son dropped a bull terrier dog, 2½ years old, over the side of a pram dinghy into a river. The dog was used to swimming and had been in the water off and on for some hours. The dog went straight down, with his four legs stretched out rigidly, and my son could follow him with his eyes for quite a distance, and without any sign of a struggle he was drowned.

Since that time I have heard of a number of cases of people drowning after diving or falling into the water where there has been no evidence of any struggle.

Perhaps laryngeal vertigo is commoner than has been supposed, not confined to elderly men, and it may be the cause of many unexplained deaths by drowning.

Liverpool

P ELDON GORST

SIR,—The type of cough leading to the condition of "laryngeal vertigo," described in your leading article of July 15 as "a hard jerky series of unproductive coughs against a closed glottis," does not correspond with my experience. It might be added that a closed glottis and the act of coughing are incompatible.

The similarity of these cases to whooping cough without the whoop is striking. The subjects of this condition cough 15–20 times before taking a breath, after the first 5 coughs no air is expelled, since only residual air remains. Hyperirritability of the air passages seems to be the immediate cause of the failure to inspire—doing which would promptly relieve the cerebral venous congestion. I have found that codeine effectively

reduces the number of spasms, which altogether after a few weeks. This suggests passing infection may have been present.

I would suggest, firstly, that a diagnosis of be considered in such cases, diagnostic aid being able from a leucocyte count and cough plot, secondly, that the term laryngeal vertigo be given. I offer in its stead "cough syncope" and "convulsions." This term would comprise phenomena occurring in whooping cough, which essentially the same.

BERNARD FINE

SCREENING TEST FOR CORTISONE SUBSTITUTES

SIR,—In your issue of July 8, Dr Abelson and Moyes reported that oral administration of e produced an eosinopenia in the circulating blood to that produced by subcutaneous injection of

It may be of interest in this connection that lingual administration of noradrenaline also produced significant eosinopenia—a fact which I have not recorded.

Isopropyl noradrenaline sulphate was used in these experiments. In people in whom injection of 0.4 mg of produced an eosinopenia of 50–60% of the initial value. 4 hours, perlingual administration of one tablet (0.0 mg noradrenaline) was followed by a drop in eosinophil 90–100% after the same time.

Oral administration of noradrenaline may therefore also be capable of producing an A T C H like action.

With regard to the eosinophil count, the following technique has given us consistent results.

Blood is drawn to the 1 mark in the leucocyte pipette diluted with an eosin solution.¹ The pipette is gently shaken thirty times, and both chambers of a Neubauer haemocytometer are filled immediately. The eosinophils in all large squares of each chamber (18 large squares) are counted within the next 3–5 minutes, and the total divided by 18 multiplied by 100, giving the number of eosinophils per c.

London W 1

DIAPHRAGMATIC HERNIA AS A CAUSE OF ANÆMIA

SIR,—In your leading article of July 29 you mention that anaemia associated with diaphragmatic hernia has been seen in children, but I should like to emphasize relatively common occurrence in childhood, but many physicians still regard it as an extreme rarity in spite of the abundant literature which has accumulated since 1918, when Downes² reported a case in a boy seven

These children usually come to notice because of increasing pallor and are treated as cases of simple anaemia for varying times before the true cause is discovered. The anaemia is usually hypochromic microcytic, but it may be macrocytic with normoblastic or megaloblastic marrow, or of a mixed type corresponding to Trowell's dimorphic anaemia. There is often no haemoglobin suggesting loss of blood in the stools, and only occasional symptoms referable to the hernia, such as recurrent vomiting. The possibility of this diagnosis should therefore always be considered in cases of anaemia in childhood which do not respond quickly to hæmatinic drugs, which relapse after an initial response.

It is difficult to accept the explanation that the anaemia is due to blood loss from hæmorrhage and many authorities, notably in France, are opposed to this view, since, in most cases, in spite of severe anaemia no bleeding point can be demonstrated, and French workers have shown that there is often no blood in the

¹ Forsham, P. H. *Thorn G. W. Prunty F. T. G., Hills A. J. Clin. Endocrinol.* 1948 8 15.
² Downes W. A. *Ann Surg.* 1918 67 748.

Many possible contributory causes have been discussed, such as deficiency of intrinsic or extrinsic ability to absorb iron, and other nutritional factors. But the gastric juice is usually normal, with an intrinsic factor, and in most cases no deficiency can be demonstrated.

Work of Cameron, Watson, and Witts² in Oxford throw some light on the aetiology of this type of anaemia, for they produce new evidence in support of an earlier disfavoured theory. In investigating the anaemia which often accompanies intestinal stricture produced a macrocytic anaemia by forming blind loops of intestine in rats, the essential feature being an obstruction of intestinal contents. They suggest that the anaemia is produced by toxins or changed bacterial flora in the blind loop which destroy or otherwise use up ironopoietic factors. Is it not possible that some mechanical factor contributes to the anaemia of gastric hernia?

I would suggest, Sir, that, your explanation of the cause is simplified, and that, although in many cases large hernia may be the main factor, deficient intake, defective absorption, and stagnation of visceral contents may also play a part.

Hospital for Sick Children
Edinburgh.

R G MITCHELL

SIGNIFICANCE OF THE DISCOVERY OF THE EFFECTS OF CORTISONE

I am fascinated by the refreshing article "Correspondence" on disease processes.

I could regret the passing of "focal sepsis" and be pained to put in a good word for it. I should be sorry if the "general adaptation syndrome" were all born, for that would excuse many, including me, from the unequal task of mastering it. But there is a possibility of interpreting the "psychosomatic diseases," I am really roused, and willingly lend a

hand. I am tempted into this tricky correspondence by R. Vennung's¹ confident reference to the "widely accepted correlation between personality types and the incidence of particular diseases, of which perhaps the best examples are ulcerative colitis, migraine, hyperacidity, and peptic ulcer." Three of these conditions have been treated surgically for many years. From the fourth or two on the list I am myself a sufferer—mildly and occasionally but unmistakably, with all the classical symptoms. In my opinion the "personality type" in these maladies is inconstant, unless we confuse personality with the mental attitude created by the disease. Relieved of their troubles by successful surgery, as from groups one, three, and four, are no different from their fellows and are indistinguishable apart. These are "perhaps the best examples."

Why then, be who doubt this statement, I would like to see a psychological study of sufficient numbers of patients at a suitable interval after the successful termination of their treatment.

University of Liverpool

CHARLES WELLS
Professor of Surgery

—There is one matter that should be mentioned in Professor Pickering's dismissal of psychosomatic disease. It is to be seen in its proper perspective. The Professor Choyce used to speak of the waters of life that flowed between the anatomy and physiology departments and the medical schools. Of only one of these is this still true and that is the

relation of the emotions to bodily health. There is a long and honourable tradition of physiological study, which academic medicine in this country has refused to carry on, either directly or by providing facilities for others. The psychiatrists have their own word for this, but it does seem remarkable that the natural curiosity of medical scientists, to put it no higher, has led to so little exploration of this field. Academic medicine may be entitled to dismiss psychosomatics for lack of evidence. In fairness it should at the same time recognise its own responsibility for the deficiency.

REGISTRAR APPOINTMENTS

SIR,—Dr Stewart, in his letter of July 15, has put in a plea for more appointments at registrar level for over-sea postgraduates. I want to commend his suggestion most strongly to hospital staff committees.

It would seem that the registrar is indeed a necessity to our hospital system under present establishments. A registrar is a postgraduate with a knowledge of his subject and bent on acquiring breadth and depth of experience. Not only from the Dominions but throughout Western Europe (and especially in Scandinavia) there are many such who are eager to work for a period in British hospitals, on my tour in Denmark this year I was asked many times how such an appointment could be arranged. I did arrange one junior appointment last year for a Danish anaesthetist, and a deal of trouble it cost me—not from higher authority or the General Medical Council (at that level the scheme worked very smoothly) but from senior hospital staff. However, the appointment was a great success, but many are turned away rebuffed or with a cold invitation to visit the hospitals as an observer, and so turn their eyes only to the United States, making both themselves and us the poorer.

If Britain is to retain her proud position in the future as a centre for world medicine, at the same time enriching her own thought with the stimulus of fresh minds, and make her full contribution to international understanding, Dr Stewart's suggestion has much to commend it, and if put into practice could result in nothing but good.

London W 4.

PHYLLIS M EDWARDS

POSTURE

SIR,—I read with interest the letter of July 15 from Dr Gellner, on the influence during childhood of the heel of the shoe and the tilt of the head.

None will dispute the desirability of a good posture, and it is easy to appreciate that the method of walking with a book on the head is effective. In order to rectify some foot disturbances I have taught many children the following simple manner of walking to obtain a good poise.

The heels, buttocks, shoulders, and head are all placed against a wall with the hands elevated high above the head. The child is then taught to stretch the hands higher still, which will normally be about another inch. This can only be done with the body fully upright, its curves straightened out and with an adequate tightening of the abdominal muscles. While the body is thus tense the arms are dropped and the shoulders relaxed, and the child is instructed to walk without stiffness, looking towards a point on a level with the eyes. This exercise does undoubtedly give a good carriage and checks certain foot disturbances without the necessity of using a book.

The subject of posture is however, more complex than it at first appears. We assume that the head erect position, being graceful, is the natural one. But in walking the natural tendency is for the trunk to precede the feet. We do not walk by placing the leg

LARYNGEAL VERTIGO

SIR,—The description of laryngeal vertigo in your leading article of July 15 is, no doubt, correct for the majority of cases. However, a prolonged bout of coughing is not necessary for the production of this syndrome, as can be seen from the following case report.

A man, aged 52, was recently seen in the outpatient department complaining of attacks of loss of consciousness. At the age of 35 he had developed asthma, to which he had since remained liable. THE DOCTOR'S GUIDE

ch has happened since 1935 when the last edition (*Medical Practitioners Handbook*) was published by the Medical Association, that revision and expansion vitable Industry, accuracy, and insight have clearly the task and the result is well worth the effort. The is originally intended as a guide to the newly qualified and his interests are still well covered by the sections tration, the descriptions of the types of practice open inside and outside the National Health Service, and er on entry into general practice. But many doctors long established in the profession, will read with and profit the chapters on practical aspects of medical on day-to-day problems, and on opportunities for duate education. The institutions—such as the , societies, the B.M.A. itself, the Medical Insurance , and the benevolent societies—which are the instru of professional coöperation are also described. The uces though prosaic will stand the doctor in daily or they include a classified list of drugs and appliances, ies under the Dangerous Drugs Acts, and some "useful es". The handbook is obtainable from the B.M.A., ch. Square, London, W.C.1, for a well spent five

DRUG OR TOILET PREPARATION?

TORS who order National Health Service patients food et preparations on the official prescription form (E.C. 10) e called on to pay for them. Yet until lately there was ognised dividing line between drugs and these other s. In May the Standing Medical and Pharmaceutical y Committees and their Scottish counterpart reported e differentiation between drugs and foods, they have drawn up general principles as a guide in deciding en drugs and toilet articles. The following should e ordered on E.C. 10. (1) Preparations of undisclosed osition. (2) Preparations normally used for toilet ses, even though they are included in the B.P. or B.P.C ples are bath salts, face or hand cream, shaving soap, paste or powder, and hair tonics, and the B.P.C rations cologne, spirit ointment of rose water and the s of stearic acid or hamamelis. (3) Proprietary prepara for which prophylactic or therapeutic claims are made y may be used for routine toilet purposes. Examples nt mudge creams, medicated soap, and special toilet rations for allergic persons.

BROADCAST POSTGRADUATE LECTURES

July 27, Prof. Richard H. Freyberg broadcast from a York wireless station a postgraduate lecture on Hormone tionship to Rheumatic Disease. This was the first of a ly series arranged by the New York Academy of Medicine series chosen from lectures delivered before the academy affiliated organisations, is intended for doctors in the York area and will be recorded for reproduction before al audiences elsewhere. The *New York Times* (suppl. 23) remarks that the public will certainly listen. "Verbal trosities will be tolerated for the sake of learning some about arteriosclerosis or the effect of rice diet in ng high blood pressure."

Dr Brain was elected the college representative on the General Medical Council and on the governing body of the Postgraduate Medical Federation.

The Bisset Hawkins medal was awarded to Sir Wilson Jameson in recognition of his services in promoting public health during the past ten years while he was chief medical officer of the Ministry of Health. The Gilbert Blane medal for 1950 was awarded to Surgeon Commander E. B. Martin, R.N. The Murchison scholarship was awarded to Dr J. C. Mitchell.

The following having satisfied the censors' board were elected to the membership.

Licences to practise were conferred upon the following 107 candidates (92 men and 15 women) who have passed the final examination of the conjoint board.

K. R. Aberdour Daniel Abse Lillian E. Ackermann Sheleagh Aldersmith R. J. Ancill M. J. Argyrides, B.H. Bass W. H. G. Batham Barbara E. Batty, H. H. G. Bell J. C. Betts Hyla M. Birks F. R. Brearley J. M. Brown B. H. Burne G. E. H. Callebaut T. H. Christie D. J. Coleman H. G. Cooper H. D. Cullimore H. J. B. Day A. R. de C. Deacock J. C. Dille Peter Dinmore W. A. W. Dutton M. A. Ebrahim H. B. Eckstein J. A. Eddington P. C. Fleming Robert Fleming J. H. G. Ford N. S. Galbraith

first in front of the body, although this is the acquired method of the mannequin. The first thing we do in walking is to incline the body forward from the ankle joint. It is interesting to notice a line of guardsmen, whose posture is beyond reproach. At the command "quick march" the whole line will be noticed to lean forward as a preliminary to the first step. Is it not possible, therefore, that the slight pitching forward of the head is a natural anticipation of the manoeuvre, and that the erect head is a state acquired either by specific exercises or the carrying of a weight upon the head? It does appear obvious that there is need to avoid obstacles immediately in front of us, and that looking straight ahead may not always be satisfactory. A child would naturally look downwards, particularly in the tottering stage.

The suggestion that the slight heel would necessarily tilt the body forward in a child cannot be accepted. The body does not bend forward any the more because we walk downhill, if anything the tendency is to throw the body weight backwards to compensate for the incline. The range of action of the ankle joint is indeed sufficient to compensate for sloping surfaces. In the average adult flexible foot a considerable range is possible without tilting the body forward, and a child has an even greater range. The toddler's slight heel can therefore have no influence on the positioning of the head.

Civilisation may be responsible for many disorders, but it is doubtful whether the toddler's small heel can be rightly blamed for bad posture.

EXCRETION OF POTASSIUM AFTER PARTIAL GASTRECTOMY

SIR,—In your issue of July 22, Mr Wilkinson and his colleagues comment on the excessive excretion of potassium that may occur soon after operation. It is tempting to suggest that this sudden loss of potassium is, like the more gradual loss of nitrogen, a result of the increased excretion of adrenal hormone after injury.¹ The loss of potassium does not seem to depend on the development of an inflammatory reaction, for it may take place with other types of injury. Albright² observed a transient rise in potassium excretion together with a rise in 17 ketosteroid excretion in a patient who, while on a metabolic balance study, received too rapid an intravenous infusion. The phenomenon has been observed after exposure. It has recently been described in dogs allowed to go into diabetic coma.³ It may be reproduced by stimulating the adrenal cortex with adrenocorticotrophic hormone (ACTH)⁴ or by giving Compound F—an adrenal steroid with "sugar hormone" activity.⁵ In these experiments the increase in excretion of potassium occurs without a rise in the serum level, so the effect of the hormone must be on the kidney. The kidney does not conserve potassium and may even actively excrete it, so a deficiency can easily arise.⁶ It is not, however, easily demonstrated, since serum levels may not fall. The liberation of adrenal hormone would also explain the sodium retention observed after operation, since sodium is retained when ACTH is given.

Obituary

IVOR ISAAC PRICE

M B LOND, F R C S

Mr Ivor Price who died on July 24, at the age of 57, was born in London and educated at Daventry Grammar School. He entered King's College Hospital School in 1920, where he had a distinguished career as an undergraduate, winning a number of prizes. In 1925 he qualified and in the following year took the M B Lond. He held the resident posts at the M B Lond and the appointments of resident medical officer at Queen Mary's Hospital to the East End, and superintendent at the Seaman's Hospital, Tilbury, taking his F R C S in 1928. The previous year he entered the London County Council hospital service; he was on the staff of Bethnal Green Hospital, St Andrew's Hospital, Bow, till in 1938 he was deputy medical superintendent and senior consultant at St Mary Islington Hospital. In 1948 he was consultant surgeon to the newly formed Waltham Hospital, an appointment which he held to the end of his death.

T St M N writes: "One could not wish for a colleague than Price. He accepted a case for a hernia with the greatest care, but he never turned away from an operation which might be of benefit to the patient, however great the surgical risk. Having taken a patient, he treated him first as an individual, and then as a surgical problem, sparing neither time nor effort for his behalf. In his resident position he saw and dealt with most of the surgical emergencies in a large hospital, and rapidly acquired tremendous experience. He soon began to specialise in gastroenterology, and he swiftly acquired a high and increasing reputation in this specialty among his colleagues in North London.

"An academic as well as a practical surgeon, he was always alive to what was new and progressive in the trends. He was a good teacher, and many of his graduate students owed much of their success to his friendly assistance. From his juniors he expected the high standard which he set himself, demanding the keenness, thoroughness, and self-sacrifice, but he was generous with his praise for the good diagnosis, the suggestion, the successful surgical performance. So and amusing, he was a great raconteur of incidents, often at his own expense. He was interested in the hospital as a whole, and many of the staff in grades regarded him as their friend. His work was his primary interest, and he could never accept the offer of his doctors to slow down and retire when the symptoms of his illness showed themselves. Indeed, he had lately taken charge of the surgical side of a large gastroenterological unit, where he was working within a few hours of his death."

Mr Price leaves a widow and a son aged five.

GEOFFREY MICHAEL FULTON BARNETT

M B A Z, F R C S, F R A C S

Dr G M F Barnett, who died at the age of 57 on July 13, while driving his car in Dunedin, was assistant surgeon to Dunedin Hospital and lecturer in clinical surgery in Otago University.

The eldest son of the late Sir Louis Barnett, first professor of surgery in Otago University, he was born in Dunedin and educated at Christ's College and Otago University. While still a student he served in G. S. during the 1914-18 war. After graduating at Otago in 1920, he came to London and he held the posts of resident medical officer at Middlesex Hospital, taking his F R C S. He returned in 1925 to Dunedin, where he practised up to the time of his death. For many years he served as a member of the War Pensions Appeal Board. A friend adds:

"Of a quiet disposition, Barnett was beloved by a wide circle of professional colleagues, and by his patients. A rugby footballer in his youth, he later was a keen bowler."

His wife, two sons, and three daughters survive. A third son was killed in the late war.

THE DOCTOR'S GUIDE

ch has happened since 1935 when the last edition *Medical Practitioners' Handbook* was published by the Medical Association that revision and expansion of the Industry, accuracy and insight have clearly been the task and the result is well worth the effort. The book originally intended as a guide to the newly qualified and his interests are still well covered by the sections on the descriptions of the types of practice open inside and outside the National Health Service and on entry into general practice. But many doctors, long established in the profession, will read with interest and profit the chapters on practical aspects of medical education, day-to-day problems and on opportunities for further education. The institutions—such as the societies, the B.M.A. itself, the Medical Insurance Society, and the benevolent societies—which are the instruments of professional co-operation are also described. The book, though practical, will stand the doctor in daily use or they include a classified list of drugs and appliances, under the Dangerous Drugs Acts, and some useful references. The handbook is obtainable from the B.M.A., 1, Wimpole Square, London W.C.1, for a well spent five shillings.

DRUG OR TOILET PREPARATION ?

Those who order National Health Service patients food
 et preparations on the official prescription form (F c 10)
 e called on to pay for them. Yet until lately there was
 ognised dividing line between drugs and these other
 s. In May the Standing Medical and Pharmaceutical
 ory Committees and their Scottish counterpart reported
 a differentiation between drugs and foods, they have
 drawn up general principles as a guide in deciding
 en drugs and toilet articles. The following should
 be ordered on F c 10. (1) Preparations of undisclosed
 osition. (2) Preparations normally used for toilet
 ses even though they are included in the B P or B.P.C
 ples are bath salts, face or hand cream, shaving soap,
 paste or powder and hair tonics and the B.P.C
 rations cologne spirit ointment of rose water and the s
 of stearic acid or hamamelis. (3) Proprietary prepara
 for which prophylactic or therapeutic claims are made
 v may be used for routine toilet purposes. Examples
 ut midge creams medicated soap, and special toilet
 arations for allergic persons.

BROADCAST POSTGRADUATE LECTURES

On July 27, Prof. Richard H. Frerberg broadcast from a New York wireless station a postgraduate lecture on Hormone relationship to Phumatic Disease. This was the first of a series arranged by the New York Academy of Medicine chosen from lectures delivered before the academy affiliated organisations, is intended for doctors in the New York area and will be recorded for reproduction before local audiences elsewhere. The *New York Times* (suppl. 23) remarks that the public will certainly listen "Verbal atrocities will be tolerated for the sake of learning some about arteriosclerosis or the effect of rice diet in high blood pressure."

Fish Conjoint Board

Having passed the final examination the following have
admitted licentiates of the Royal Colleges of Physicians
Surgeons of Edinburgh and the Royal Faculty of
Physicians and Surgeons of Glasgow

Students of the Glasgow School of Medicine
 E. Aitken, Eleanor K. Althorp, R. F. Armstrong, J. G. Bhatt,

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Aug 8, at 3.30 p.m., Prof Homer Smith, director of the department of physiology at the New York University and Bellevue medical centre, will deliver a lecture in the anatomy lecture theatre of Edinburgh University. He is to speak on the Development of Modern Renal Physiology.

Congress of Internal Medicine

The first International Congress of Internal Medicine will be held in Paris from Sept 10 to 14, under the presidency of Prof André Lemerle. Further information may be had from Prof L Justin Besançon, 38, rue Barbot-de Jouy, Paris VII.

The Heart Televised

Last Monday Dr J L D Silva, professor of physiology at the London Hospital Medical College, and Dr John McMichael, professor of medicine at the Postgraduate Medical School of London, took part in a television programme on how the heart works, how it can go wrong, and how heart-diseases are treated. Patients, a pregnant woman, medical students, and animated diagrams were used to explain and demonstrate the various points, the heart sounds being recorded and amplified by an apparatus designed by Dr Bernstein. The programme was the eighth in the 'Matters of Life and Death' series. It was arranged by Dr Brian Stanford and was produced by Andrew Miller-Jones. Future programmes will deal with the anaemias and tonsillectomy.

Appointments

BODEN, G W, D.S.C. Lond., M.R.C.P., F.F.R. D.M.R., London Hospital.

BUCHANAN, J W, M.A. Camb., M.D. Edin., M.R.C.P.E. vician, East Fifo group of hospitals.

CORRIHAN, MAURICE, M.B., D.S.C. vici consultant of hospitals in Dowsbury, Dabney, and Mirfield hospitals, ment committee group.

DRUMMOND, WILLIAM, M.B.E., M.B. Edin., F.R.C.S.E. vici group of hospitals.

DUNDAS, JOSEPH, M.D. vici M.R.C.P.I. D.M. vici psychiatrist, Menston Hospital, Leeds.

FISHER, R F W, M.B. Belf., D.P.H., D.I.L. chief vici Eastern Area Gas Board.

FLAVELL, GEOFFREY, F.R.C.S. M.R.C.P. asst. surgeon, department London Hospital.

HAMILTON, J C M, M.B. Edin., F.R.C.P.F. senior vici East and West Fifo groups of hospitals.

HENDERSON, R G, M.B. B.S.C., Glasg. F.R.C.S.E. vici Falkirk and District Royal Infirmary.

MACKIE, J R M, M.D. Aberd. M.R.O.P. D.M. consultant, vici Menston Hospital, Leeds.

Births, Marriages, and Deaths

BIRTHS

BEAL—On July 25, in London, the wife of Dr J H Beal—
CLAY—On July 20, at Ilkley, the wife of Dr H F Clay—a daughter.

MACKEY—On July 16, at Gosherton, Lincs, the wife of E P Mackenzie—a son.

MCLEISH—On July 24, in London, the wife of Dr Alastair McL—
—a daughter.

SCADDING—On July 27, the wife of Dr J G Scadding—a daughter.
WHELDON—On July 24, the wife of Mr F T Wheldon—
—a son.

MARRIAGES

BARRON—HALTON—On July 22, at Carlisle, Arthur Barron—
to Prudence Halton, F.R.C.S.E.

DUNLOP—WARNER—On June 23, at Dibrugarh, Assam—
John Dunlop, M.B. vici M.R.C.P.E. to Barbara Warner.

STELL—DAVIES JONES—On July 29, at Chester, John Stell, A.T.D., to Eleanor Davies Jones, M.B.

DEATHS

BARNETT—On July 14, at Dunedin, New Zealand, Go Michael Fulton Barnett, M.B. vici F.R.C.S. F.R.A.C.S.

COURT—On July 29, at Ilminster, Somerset, Christopher C Court, M.B. Birm., D.P.H.

Downs—On July 21, George Edward Downs, M.A., F.M.C. aged 64.

EDMONSTON—On July 20, at Cheltenham, Charles C Edmonston, M.B. Edin., F.R.C.S.F.

MIRCHELL—On July 21, Marjorie Hall Mitchell, M.B. Glasg. vici M.O.

Morrison—On July 25, at Chapel-en-le Frith, Edward Moll, L.L.M. vici M.O.

Ruest—On June 26, at Cape Town, Montague Ruest, L.L.M. vici M.O.

SOLLY—On July 26, at Harrogate, Ernest Solly, M.B. Lond., D.P.H., aged 87.

CORRIGENDA Development of Modern Renal Physiology. In the fifth paragraph of our annotation last week the amount of glomerular filtrate formed daily should have been stated as 180 litres (not 18), and the amount of passed in the urine as 80 g (not 0.8).

Honorary Degrees—The University of Liverpool has conferred on Dr E A Gregg and Dr C O Stallybrass the honorary degree of M.D. (and not the degree of LL.D. as stated in issue of July 22).

Intestinal Parasites of Man in Great Britain. In account of the meeting of the B.M.A. section of tropical medicine (July 29 p 186) Brigadier J S K Boyd reported as saying that non pathogenic organisms, such as *B. coli*, may precipitate tissue invasion with *Entamoeba histolytica*. We understand that he referred particularly to the presence of enterococci and clostridia (rather than *Bact. coli*) together with *E. histolytica* to produce lesions of the intestinal membrane.

RESPONSE TO ADRENOCORTICOTROPIC HORMONE AND CORTISONE* PERSONS WITH CARCINOMA, LEUKÆMIA, AND LYMPHOSARCOMA

INSTRUCTORS IN GENERAL PATHOLOGY

UNIVERSITY OF HAVANA

At the present time there are no positive medicinal agents for carcinoma, leukæmia, or lymphosarcoma. Many promising agents are being studied, such as rogen mustard, the so-called folic-acid antagonists, and radioactive compounds, but none of these can be considered true cures, because they are not based on a reversal of the underlying chemical disturbance. In any instance the body has to cope simultaneously with disease and with the remedy. Without getting into discussion of such agents as surgery, X rays, and hormones, which may give relief by cellular destruction of tumour, we believe that for the eventual control of cancer it is more important to make every effort to develop a positive chemical understanding of the disease. To us, this is the crux of the matter. An intelligent scientific approach would seem to require the concerted action of chemists to study the blood and other tissues of an affected person before, during, and after specific experimental procedures.

We (Spies et al. 1949, 1950) and others (Pearson et al. 1949, Farber et al. 1949, Taylor and Morris 1949) have administered either pituitary adrenocorticotrophic hormone (A.C.T.H.) or synthetic 'Cortisone' acetate to selected persons with these diseases. The effects of these substances are unpredictable, and they offer no cure under these conditions in the immediate future. Under certain circumstances, however, the symptoms have been much ameliorated that it seems desirable to make a report.

Our patients were selected after careful histopathological examinations. Of the three patients with carcinoma two had had surgical procedures and X-ray therapy could not be benefited further, while the third had seemed to have the carcinoma of his lip excised. All excruciating pain and were incapacitated. Final lesions were that the primary site of the lesion must be visible to the unaided eye, that the patients must be cooperative, and that they should agree to have biopsies whenever necessary. The five patients with leu-

kæmia were selected arbitrarily after determining that they had acute leukæmia and that they had to have at least three blood transfusions weekly, four of them had lymphatic leukæmia and one had myelogenous leukæmia. The two patients with lymphosarcoma were selected because they had great pain, were unable to work, and wanted to cooperate in our studies.

Observations

CARCINOMA

Of the patients with carcinoma two were treated with synthetic cortisone acetate and one with pituitary A.C.T.H. In the two patients who received cortisone the condition was worse, and the improvement less than in the patient given A.C.T.H. In both of them the involved tissues of the tongue, mouth, and regional lymph-nodes were matted into a hard firm mass which protruded several centimetres. Each patient was given a total of 3 g. of cortisone in divided doses of 150 mg. daily intramuscularly. Following this therapy they had a striking increase in sense of well being and appetite; the amount of narcotics used could be reduced to about one tenth of what was previously necessary, and the patients became interested in carrying on a normal life. But histological examination showed no change in the neoplasms which were composed of large anaplastic epithelial cells of squamous type, with hyperchromatic nuclei, numerous mitotic figures, and involvement of the stroma. Despite the large amount of cortisone administered, neither patient developed any evidence of water or salt retention, and when the injections were discontinued there was no diuresis or loss of body weight.

The following is an account of the response of the patient given A.C.T.H.

A white man, aged 60, complained of swelling and pain of the right side of the lower lip. It had begun nine months previously and had grown progressively worse, but he had refused operation. The lesion, which was hard and sensitive, was a large ulcerated area covered with greyish white exudate, the crater was about 1 cm. across and its edge was slightly elevated. The entire area of involvement was rounded and about the size of a walnut. He was unable to spit and he drooled continuously. His false teeth had been broken for five years, and the break was exactly opposite the central portion of the crater of the tumour. (To evaluate the effectiveness of therapy, the dentures were not changed during our studies.) The lymph glands on the right side of the neck were firm and enlarged; the largest being about 1 cm. long, they were not tender. The tongue and buccal mucosa membrane appeared normal.

A biopsy specimen was described as follows: "Tumour masses growing in cords and strands almost completely replacing the dermal surfaces. These tumour masses tend to keratinise at their centres. There is marked inflammatory infiltration around the tumour strands. Diagnosis: squamous-cell carcinoma of the lip, grade II. The blood levels were within normal range. The pulse, temperature and respiration were normal and the blood pressure ranged from 122/80 to 130/80 mm. Hg.

The patient was given a total of 270 mg. of A.C.T.H. in five days, administered in 15 mg. doses six hourly. Twelve hours after the first injection the size of the lesion had noticeably decreased and it was considerably less sensitive. He volunteered that he had more energy than for several months and for the first time in many weeks had a desire for food. Next day the lesion was still smaller and there was less exudate from the crater. It was not painful and he could move his lip with ease and without pain though it was still sensitive to touch. Therapy was discontinued after five days because no more A.C.T.H. was available. During therapy the blood pressure increased slightly, ranging from 144/74 to 150/82; after therapy was discontinued, it returned to the initial level. The blood values remained within normal range.

The report on a second biopsy specimen was: "Section through the specimen shows a thin margin of relatively normal-appearing squamous epithelium. In the central portion there is an interruption with downgrowth of broad sheets of squamous epithelium. These show some variation in

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Aug 8, at 3.30 p.m., Prof Homer Smith, director of the department of physiology at the New York University and Bellevue medical centre will deliver a lecture in the anatomy lecture theatre of Edinburgh University. He is to speak on the Development of Modern Renal Physiology

Congress of Internal Medicine

The first International Congress of Internal Medicine will be held in Paris from Sept 10 to 14, under the presidency of Prof André Lemoigne. Further information may be had from Prof L. Julien Besançon, 38, rue Barbet-de-Jouy, Paris VII.

The Heart Televised

Last Monday Dr J L D Silva professor of physiology at the London Hospital Medical College, and Dr John McMichael, professor of medicine at the Postgraduate Medical School of London took part in a television programme on how the heart works, how it can go wrong, and how heart-diseases are treated. Patients a pregnant woman, medical students and animated diagrams were used to explain and demonstrate the various points, the heart sounds being recorded and amplified by an apparatus designed by Dr Bernstein. The programme was the eighth in the "Matters of Life and Death" series. It was arranged by Dr Brian Stanford and was produced by Andrew Miller-Jones. Future programmes will deal with the anemias and tonsillectomy.

2—Effect of A.C.T.H. on the erythrocyte-sedimentation rate in a case of acute leukemia.

ch had been 38.2°C on admission, fell to 36°C on the second of therapy and did not rise above 36.4°C while he was giving the injections. The pulse rate, which was 80 at the beginning of therapy, ranged between 128 and 140 throughout therapy. The average respiration rate was 18 before, during, and after therapy. Before therapy the blood pressure was 150/90. By the eleventh day it had increased to 120/60, and the fourteenth day it was 130/60. His body weight, which was 36 lb at the beginning of therapy, increased to 40½ lb, but he did not develop any clinical edema and had no diuresis after the A.C.T.H. was discontinued. On the second day of therapy he got out of bed, played around the ward, and was interested in everything going on. From that day he ate all the food on his trays, improved steadily in strength and vigor, and was as active as a normal child.

Twenty-four hours after the injections of A.C.T.H. were discontinued he was weak, bleeding, crying, and obviously apathetic. Next day a smear of the peripheral blood showed polymorphonuclear leucocytes 28%, band cells 1%, eosinophils 1%, lymphocytes 65%, myelocytes 1%, and lymphoblasts 4%. After forty-eight hours without injections of A.C.T.H. he was started on 80 mg intramuscularly in doses of 40 mg every six hours. On the second day there was a striking clinical improvement. He began eating well and playing again. On the ninth day all the examining physicians concurred that he now had a so-called "moon face" (compare fig. 3 with fig. 4). By this time his body weight was 6 lb greater than at the beginning of therapy but he had no pitting edema at the ankles. His condition was such that the only hope was to continue the A.C.T.H. injections, so a daily dosage level of 80 mg was continued for ten days. Then it was reduced to the following total amounts daily, injected in divided amounts every six hours: 40 mg for one day, 30 mg for five days, 20 mg for one day, 15 mg for three days, and 12 mg for eight days. Before the reduction in dose the blood counts were: red cells 5.12 million, white cells 9300, hemoglobin 2 g (86%), and reticulocytes 0.4%. A smear of the peripheral blood showed polymorphonuclear leucocytes 14%, band cells 4%, basophils 1%, eosinophils 3%, and lymphocytes 21%. The platelet count was 656,700. The sedimentation rate with correction was 5 mm. per hour (see fig. 2). The bone marrow showed a striking change toward normal but there were some abnormal collections of white elements.

A.C.T.H. injections were discontinued after he had a total of 1750 mg in forty-three days. By this time the moon face was more pronounced and his body weight, which was 36 lb before therapy, had increased to 45 lb. At this time he developed some acne limited to a small area on the chin. In the two weeks that elapsed after A.C.T.H. therapy was discontinued the red-cell count, white cell count and hemoglobin remained essentially unchanged. The day after therapy was discontinued the differential count showed polymorphonuclear leucocytes 31%, metamyelocytes 1%, basophils 1%, lymphocytes 67%. In the next four weeks the sedimentation rate with correction, varied between 30 and 51 mm. per hour (see fig. 2). The moon face and the acne persisted, his body weight increased to 50 lb (no evidence of water or

sodium retention). He felt well and had a good appetite until the twenty-ninth day after therapy was discontinued. Then he suddenly relapsed. His temperature was 39.5°C, his pulse and respiration rates were rapid. Many immature cells were in his peripheral blood and he began bleeding from the gum margins. At the time of relapse the blood counts were: red cells 4.64 million, white cells 19,500, hemoglobin 12.4 g (81%), and reticulocytes 0.2%. A differential count showed polymorphonuclear leucocytes 20%, metamyelocytes 4%, band cells 8%, and lymphocytes 68%. The sedimentation rate corrected was 52 mm. per hour.

A.C.T.H. in divided doses was started again. At the present time, after nine days of therapy, his response is similar to that seen in the two previous periods of therapy.

LYMPHOSARCOMA

The two patients with lymphosarcoma responded promptly and similarly to synthetic cortisone acetate. Both had a great gain in strength, and a desire to eat and to work, and in both the symptoms disappeared. One remained essentially free of symptoms for about three weeks and the other for about six weeks before the relapse occurred. The following case history is representative.

A man of 59, with typical lymphosarcoma, was carried to the hospital complaining of weakness, "fever," generalised itching, pain in his abdomen, and "swollen glands" in his neck.

Two years before admission he had suddenly developed acute abdominal pain which rapidly became more and more severe. A physician had given him medicine which relieved

Fig. 3—Patient before intensive treatment with A.C.T.H.

Fig. 4—Patient after treatment. Note development of round face.

it within a few hours. A few weeks later he had noticed enlargement of the glands in his neck. Because of weakness, frequent pains in the back and abdomen, and (every three or four weeks) periods of "chills and fever" in the late afternoon and evening he had been unable to work since the onset of his illness. Early in its course he had lost his appetite and since then he had eaten little. His body weight had decreased by 29 lb in the two years.

He appeared profoundly ill and was unable to walk. There were enlarged lymph nodes on both sides of the neck and tumour masses were felt in the umbilical region, the left iliac fossa, and the right side of the abdomen. Biopsy of the nodes showed typical lymphosarcoma.

The initial peripheral blood findings were: red cells 4.12 million, white cells 8500, hemoglobin 8.6 g (56%), and reticulocytes 0. The differential count showed polymorphonuclear leucocytes 60%, basophils 1%, eosinophils 14%, lymphocytes 13%, and myelocytes 12%. The erythrocyte sedimentation rate, with correction, was 49 mm. per hour.

He was given 300 mg of cortisone intramuscularly daily for three days and then 150 mg daily for fourteen days. On the third day of therapy he felt considerably better, the itching of the skin was less and his strength greater. On the sixth day he began walking around the ward. His strength increased and the abdominal pain decreased daily. Slight edema of the face developed on the tenth day, and next day there was moderate edema of the feet and ankles. By this time he weighed 11 lb more than at the beginning of therapy and the twenty-four hour output of urine had decreased from 2000–2300 ml to 1000–1200 ml.

nuclear size occasional mitotic figures In an occasional area there is keratohyalin production with formation of small pearls Around the invading squamous epithelial cells there is some chronic inflammation Diagnosis squamous cell carcinoma grade II" (see fig 1)

Four months after A.C.T.H. therapy was discontinued the lesion measured 12 x 7 mm Though still sensitive to touch, it was not painful otherwise At this time he was given a second series of injections of A.C.T.H. until he had received 576 mg during twenty four days, administered intramuscularly in 8 mg doses eight hourly On the second day there was a suggestion of less thickness of the lesion Gradually it became smaller and less firm By the eleventh day the patient was certain that the lesion was only half the size it had been at the beginning of treatment and he said that his lip felt normal, the ulcerated area had decreased to the size of a pinhead By the twentieth day all pain and soreness had disappeared At this time he went back to work for the first time in over a year On the sixteenth day of therapy he had developed slight oedema of the feet and ankles which disappeared the following day The blood pressure before therapy ranged from 108/70 to 118/74, and during therapy from 136/70 to 136/76, after the A.C.T.H. was discontinued, it returned to the initial level The blood levels, temperature, and pulse and respiration rates remained normal throughout

The biopsy report after treatment was "Section through the specimen shows a margin of normal appearing squamous epithelium This is interrupted along one edge by the down growth of masses of squamous epithelium These are very adult, are producing keratohyalin, and forming pearls They extend down to the lower margin of the biopsy specimen There is some acute and chronic inflammation associated with the lesion. Diagnosis squamous cell carcinoma of the lip, grade II, acute and chronic inflammation"

Though A.C.T.H. therapy was discontinued six months ago, the patient insists, and correctly, that the lesion is still decreasing in size He has been advised repeatedly to have it excised, but so far he has refused to do so

LEUKÆMIA

The results of administration of pituitary A.C.T.H. to the five patients with leukæmia were extremely variable One patient died on the fourth day without being benefited in any way which we could determine The patient with the myelogenous leukæmia had a great clinical and moderate hematological response but developed hallucinations after 2500 mg of A.C.T.H. had been given in twenty five days By that time her bone

marrow, which before therapy had been almost replaced by leukæmic cells, was about one-half element and one half leukæmic When she had hallucinations treatment was discontinued and disappeared within twenty four hours A.C.T.H. was resumed after a three day interval at the dosage level of 25 mg four times a day, and half reappeared within forty-eight hours From that on, it was impossible to give her 100 mg of A.C.T.H. twenty four hours without the recurrence of hallucinations Hence it was a losing fight and she died within third month of her illness The red blood-cells and hæmoglobin increased somewhat till the time of her death

The other three patients with leukæmia are living One of them, under observation for a year, has had a series of A.C.T.H. injections, each lasting fourteen days at a dosage level of 100 mg in twenty four hours. No untoward symptoms developed, the enlarged lymph nodes in the neck and axillæ decreased in size, and the bone marrow became much more normal in appearance though it still contained some abnormal cells. Five months after the first period of A.C.T.H. therapy symptoms recurred and she was treated again with similar results Now, six months after the last series of injections, another relapse seems imminent The fourth patient had rheumatoid arthritis as well as leukæmia and was given 40 mg of A.C.T.H. four times a day for ten days Within three days of the first injection the symptoms of arthritis decreased and the bone marrow appeared somewhat more normal His reticulocytes rose rapidly during the next week, and the red-cell count and the hæmoglobin content of the blood increased to within normal limits within three weeks, whereas before treatment it had been necessary to give him three transfusions a week At the present time transfusions are unnecessary We see him frequently, for we suspect that he will relapse rather promptly because of the many abnormal young cells in the peripheral blood and in the bone-marrow

The fifth case requires a more detailed report.

A boy, aged 7 years, was admitted to the hospital with acute leukæmia He had suddenly become ill three weeks previously, acute lymphatic leukæmia had been diagnosed and he had had three or four transfusions weekly When admitted, he was bleeding profusely from nose and gums and was semicomatose, refusing food and water when aroused

The initial peripheral blood findings in the hospital were: red blood cells 2.55 million, white blood-cells 6350, hæmoglobin 8.4 g per 100 ml (54%), and reticulocytes 0.6%. A study of the blood smear 23% of the white cells were as belonging to the polymorphonuclear leucocyte series, 54% as belonging to the lymphoid series, the remainder being unclassified. The cells were so immature that they could not be classified. The blood platelet count was 50,820 The sedimentation rate, with correction, was 64 mm per hour Sternal punctures were made repeatedly and marrow was obtained with difficulty each time Microscopic examination showed no areas of normal bone marrow and many areas characterized by clusters of white cells of various ages, sizes, and shapes. Nearly all were immature, some were recognised as being of the lymphoblastic series A few tiny areas of normal elements were seen

As soon as the baseline observations were completed, patient was given A.C.T.H. (Armour Standard) intramuscularly in sterile physiological solution of sodium chloride, in dose 10 mg every six hours This therapy was continued each day for fifteen days during which time he had no transfusions. On the third day the bleeding ceased, and the reticulocyte count was 6.4% The reticulocytes peaked at 18% on the fourth day, and at the end of the fifteen days the blood-counts were: red cells 3.38 million, white cells 5350, hæmoglobin 11.5 (59%), and reticulocytes 5.0% A smear of the peripheral blood showed polymorphonuclear leucocytes 74%, lymphocytes 25%, and one unclassified cell The platelet count 122,000 Sternal puncture showed a striking change in bone marrow many normal areas of blood regeneration apparent though clusters of abnormal white-cell proliferation (leukæmia) were also found The sedimentation rate, correction, was 15 mm per hour (see fig 2) The

Fig 1.—Squamous-cell carcinoma grade II.

1—Effect of A.C.T.H. on the erythrocyte-sedimentation rate in a case of acute leukemia.

had been 38.2°C on admission, fell to 36°C on the second of therapy and did not rise above 36.4°C while he was using the injections. The pulse rate, which was 80 at the beginning of therapy, ranged between 128 and 140 throughout. The average respiration rate was 18 before, during, and after therapy. Before therapy the blood pressure was 120/80, by the eleventh day it had increased to 120/60, and by the fourteenth day it was 130/60. His body weight, which was 36 lb at the beginning of therapy, increased to 40 1/2 lb, and he did not develop any clinical edema and had no diuresis. The A.C.T.H. was discontinued. On the second day of therapy he got out of bed, played around the ward, and was interested in everything going on. From that day he ate all food on his trays, improved steadily in strength and weight, and was as active as a normal child.

Twenty-four hours after the injections of A.C.T.H. were discontinued he was weak, bleeding, crying, and obviously ill. Next day a smear of the peripheral blood showed polymorphonuclear leucocytes 28%, band cells 1%, eosinophils 1%, lymphocytes 65%, myelocytes 1%, and lymphocytes 4%. After forty-eight hours without injections of A.C.T.H. he was started on 80 mg intramuscularly in doses of 40 mg every six hours. On the second day there was a striking clinical improvement. He began eating well and playing again. On the ninth day all the examining physicians concurred that he now had a so-called "moon face" (compare fig. 3 and fig. 4). By this time his body weight was 6 lb greater than at the beginning of therapy but he had no pitting edema of the ankles. His condition was such that the only hope was to continue the A.C.T.H. injections, so a daily dosage level of 80 mg was continued for ten days. Then it was reduced to 40 mg following total amounts daily, injected in divided amounts every six hours: 40 mg for one day, 30 mg for five days, 20 mg for one day, 15 mg for three days, and 12 mg for five days. Before the reduction in dose the blood counts were: red cells 5.12 million, white cells 9300, haemoglobin 12 g (86%), and reticulocytes 0.4%. A smear of the peripheral blood showed polymorphonuclear leucocytes 60%, band cells 4%, basophils 1%, eosinophils 3%, and lymphocytes 21%. The platelet count was 656,700. The sedimentation rate with correction was 5 mm per hour (see fig. 2). The bone marrow showed a striking change toward normal but there were some abnormal collections of white elements.

A.C.T.H. injections were discontinued after he had a total of 750 mg in forty-three days. By this time the moon face was more pronounced and his body weight, which was 36 lb before therapy, had increased to 45 lb. At this time he developed some acne limited to a small area on the chin. In the next few weeks that elapsed after A.C.T.H. therapy was discontinued the red-cell count, white-cell count, and haemoglobin remained essentially unchanged. The day after therapy was discontinued the differential count showed polymorphonuclear leucocytes 31%, metamyelocytes 1%, basophils 1%, eosinophils 3%, lymphocytes 67%. In the next four weeks the sedimentation rate, with correction, varied between 30 and 51 mm per hour (see fig. 2). The moon face and the acne persisted, his weight increased to 50 lb (no evidence of water or

sodium retention). He felt well and had a good appetite until the twenty-ninth day after therapy was discontinued. Then he suddenly relapsed. His temperature was 39.5°C, his pulse and respiration rates were rapid. Many immature cells were in his peripheral blood and he began bleeding from the gum margins. At the time of relapse the blood counts were: red cells 4.64 million, white cells 19,500, haemoglobin 12.4 g (81%), and reticulocytes 0.2%. A differential count showed polymorphonuclear leucocytes 20%, metamyelocytes 4%, band cells 8%, and lymphocytes 68%. The sedimentation rate corrected was 52 mm per hour.

A.C.T.H. in divided doses was started again. At the present time, after nine days of therapy, his response is similar to that seen in the two previous periods of therapy.

LYMPHOSARCOMA

The two patients with lymphosarcoma responded promptly and similarly to synthetic cortisone acetate. Both had a great gain in strength, and a desire to eat and to work, and in both the symptoms disappeared. One remained essentially free of symptoms for about three weeks and the other for about six weeks before the relapse occurred. The following case history is representative.

A man of 59, with typical lymphosarcoma, was carried to the hospital complaining of weakness, "fever," generalised itching, pain in his abdomen, and "swollen glands" in his neck.

Two years before admission he had suddenly developed acute abdominal pain which rapidly became more and more severe. A physician had given him medicine which relieved

Fig. 3—Patient before intensive treatment with A.C.T.H.

Fig. 4—Patient after treatment. Note development of round face.

it within a few hours. A few weeks later he had noticed enlargement of the glands in his neck. Because of weakness, frequent pains in the back and abdomen, and (every three or four weeks) periods of "chills and fever" in the late afternoon and evening he had been unable to work since the onset of his illness. Early in its course he had lost his appetite and since then he had eaten little. His body weight had decreased by 29 lb in the two years.

He appeared profoundly ill and was unable to walk. There were enlarged lymph nodes on both sides of the neck, and tumour masses were felt in the umbilical region, the left iliac fossa, and the right side of the abdomen. Biopsy of the nodes showed typical lymphosarcoma.

The initial peripheral blood findings were: red cells 4.12 million, white cells 8500, haemoglobin 8.6 g (56%), and reticulocytes 0. The differential count showed polymorphonuclear leucocytes 60%, basophils 1%, eosinophils 14%, lymphocytes 13%, and myelocytes 12%. The erythrocyte sedimentation rate, with correction, was 49 mm per hour.

He was given 300 mg of cortisone intramuscularly daily for three days and then 150 mg daily for fourteen days. On the third day of therapy he felt considerably better. The itching of the skin was less and his strength greater. On the sixth day he began walking around the ward. His strength increased and the abdominal pain decreased daily. Slight edema of the face developed on the tenth day, and next day there was moderate edema of the feet and ankles. By this time he weighed 11 lb more than at the beginning of therapy and the twenty-four hour output of urine had decreased from 2000–2300 ml to 1000–1200 ml.

At the end of therapy the peripheral blood findings were red cells 5.18 million, white cells 15,950, haemoglobin 10.8 g (70%), and reticulocytes 0. The differential count showed polymorphonuclear leucocytes 79%, metamyelocytes 1%, band cells 3%, lymphocytes 12%, and myelocytes 5%. The sedimentation rate, with correction, was 18 mm per hour. On the fifth day of therapy the eosinophils disappeared from the circulating blood and they did not reappear until seven days after therapy was discontinued. At this time the white cell count was 8950 and the eosinophils 3%. Seven days after therapy was discontinued the white cell count was 9600 and the eosinophils 5%.

Throughout the period of study the temperature varied between 36.0° and 37.9°C, the pulse rate between 88 and 120, and the respiration rate between 18 and 24. The blood pressure, which before therapy was 130/80, increased to 180/90 on the ninth day and varied between this level and 170/80 until injections of cortisone were discontinued. In the week after this it returned to the initial level.

Two days after the cortisone injections ceased the clinical evidence of the oedema disappeared, and nine days later the patient's weight was the same as before therapy. The lymph node enlargement in the neck decreased by at least 75% during the administration of cortisone and the swelling continued to subside for some time after it was discontinued, but biopsy showed that characteristic lymphosarcoma was still present. Eighteen days after therapy was discontinued the generalised itching of the skin reappeared and the abdominal pain returned. After forty-five days without therapy the blood values were red cells 4.50 million, white cells 11,500, haemoglobin 10.5 g (68%), and reticulocytes 0. The differential count was polymorphonuclear leucocytes 71%, band cells 3%, eosinophils 4%, and lymphocytes 22%. The sedimentation rate with correction was 58 mm per hour.

By this time the patient was having very severe abdominal pain and was so weak that he was unable to get out of bed. Accordingly it was decided to give him another series of injections. He was given 300 mg of synthetic cortisone acetate intramuscularly the first day and 150 mg on each of the following thirteen days. Within six hours of the first injection he began to feel better and to have less pain. The pain continued to subside and it disappeared by the eighth day. The nodes under his arm had then decreased in size. At the present time, ten days after therapy was discontinued, he is still free of pain.

On the last day of therapy the red cell count was 5.07 million, the white-cell count was 18,750, the haemoglobin was 11.3 g (73%), and the reticulocytes were 1.2%. The differential count was polymorphonuclear leucocytes 75%, metamyelocytes 1%, band cells 2%, eosinophils 1%, lymphocytes 18%, myelocytes 1%, and monocytes 2%. The sedimentation rate with correction was 32 mm per hour. The blood pressure before therapy was 120 to 130/70, on the eleventh day it increased to 170/100 and it gradually returned to the initial level after treatment was discontinued.

He has obtained light work and claims that he is able to do it without difficulty.

Summary and Conclusions

Three patients with inoperable squamous cell carcinoma, five with acute leukaemia, and two with lymphosarcoma were given either pituitary A.C.T.H. or synthetic cortisone acetate. In nine of the ten cases the symptoms were promptly ameliorated, the intense pain disappeared in six and decreased in three. In each of these nine patients the lesions dwindled in size. One patient with leukaemia died on the fourth day of treatment without having had any apparent benefit.

The patient with carcinoma of the lip became entirely free of pain and was able to resume his occupation as a carpenter. The other two patients, who had more extensive metastatic carcinoma, became much more cheerful and had much less pain. The involved lymph nodes decreased in size and they required much smaller amounts of narcotics for complete relief of pain. In each of these cases the lesions decreased but tumour cells remained.

The four patients with acute leukaemia who had some improvement responded very differently. In one the improvement was definite but not great, two improved a great deal, and one improved so much that it was difficult to find evidence of pathological cells.

The appetite of these patients became voracious. The outlook was one of mild elation, and from the day A.C.T.H. was started we did not have to give borrowed blood.

In both patients with lymphosarcoma the size of involved glands decreased rapidly when cortisone was given. The fever disappeared and a surge of weight followed. One of these patients remained free of symptoms for three weeks, the other for six weeks. When symptoms started to return, the patients were treated again with similar results. The underlying lymphosarcoma did not change as far as could be seen by histopathological technique.

The variability in response of patients with carcinoma, leukaemia, or lymphosarcoma may be due to the length of illness, length of treatment, or many factors. But if the results are variable and unpredictable, A.C.T.H. and cortisone are nevertheless promising for medical investigators in this field. Certainly changes occur in the body during their administration. Since we had objective evidence in each of the patients that the disease did not disappear, it seems well to fit this into our working hypothesis, which is: the body of the person who does not have carcinoma, leukaemia, or lymphosarcoma the glands are capable of producing protective substances from materials in the foods. It is of the utmost importance to find out the precise nature of these materials so that we can ascertain the effect of the glands in making them. How are we to maintain a chemical balance within the body to prevent these diseases developing? After all, they are overgrowths of tissue which arise from normal tissue and appear to serve no useful purpose. The cause is unknown. There is no lack of theories, but when one has finished discussing these, one still has not come to any conclusion. What is the chemical difference between the malignant tumour and the tissue from which it arises?

What happened to the abnormal cells when A.C.T.H. and cortisone were administered? Was the chemical condition of the body changed so that the activity of these cells was reduced? Does that not account for the decrease in size and the decrease of pain? The answer is not obvious. When we searched long enough microscopically, we still could find neoplastic or abnormal tissue, yet it was relatively much less. Why did it diminish in quantity? We could not tell from a microscopic study whether the process was "coming or going." We could not tell microscopically whether the balance was in favour of success or failure. What determines this delicate mechanism? In what way are the cells different from normal cells? What happens to the person who has hidden neoplastic cells which he lives over a period of years only to reappear in identical form after a long interval? Has not that person's body chemistry changed while those cells he hidden in the body throughout the years? Is there a mechanism which retards the development of a latent tumour cell? Will a person with neoplastic potentialities have them throughout his life? Though the administration of A.C.T.H. or cortisone causes neoplastic tissues to dwindle in size, a multitude of hidden abnormal cells still remain in the tissues. Will they not be called forth again as soon as the chemistry is restored to its original state? Is the what might be termed a deferred carcinoma, deferred leukaemia, or deferred lymphosarcoma? Then, is not the major problem the lack of defence within the body against these cells?

LUNG CARCINOMA IN ICELAND*

NIELS DUNGAL

M D Iceland

PROFESSOR OF PATHOLOGY UNIVERSITY OF ICELAND

PULMONARY carcinoma has apparently been on the rise in most civilised countries during the last few decades, and the increase has been in absolute numbers as well as in relation to other growths. At the beginning of this century the disease seems to have been rare, as following reports, cited by Huguennin (1928), indicate

Author	Place	Dates	No of necropsies	Cases of lung cancer No	% of total
Wiskul	Lemberg	1854-1896	11 400	40	0.35
Wiskul	Lemberg	1896-1903	24 000	17	0.08
Wiskul	Lemberg	1896-1903	7006	6	0.085
Wiskul	Petrograd	1905-1914	16 047	61	0.38

The average incidence in these four series is only 0.22% of all necropsies. When we compare the more recent figures stated by Fischer (1931) we see that the position has changed greatly.

Budapest	Helsingfors	London
(% of all necropsies)	(% of all necropsies)	(% of all necropsies)
9-23 2.67	1905-09 4.5	1923 6.76
24-27 6.65	1910-14 6.2	1924-28 14.15
27-28 8.1	1915-19 8.5	
	1920-24 12.9	
	1925-29 15.0	

In some places—e.g., Stanford, California (Eloesser 1925)—the proportion of lung cancer has reached 20% of all carcinomas. The rise in incidence seems to be continuing up to the present day, and Churchill (1948) states that in the U.S.A. pulmonary cancer is now almost as common as cancer of the stomach. Tudor Edwards (1942) has little doubt that the increase in lung carcinoma is real, though some writers think it only apparent. Peery (1940) contended that many lung cancers which were classed as metastatic when lung carcinoma was considered a rare disease were actually primary tumours. Certainly some growths which were formerly looked on as extrapulmonary—e.g., "endothelioma of

Based on an address delivered at the centenary meeting of the Hungarian Medical Association in Budapest, 1948

TABLE I—ANALYSIS OF CASES OF PULMONARY CARCINOMA

Case no.	Year	Age (yr)	Sex	Site and type of growth
1	1933	50	M	Fist size growth in left upper lobe. Brain metastasis. Hist. bronchio-columnar.
2	1933	49	M	Diffuse growth in right lower lobe enveloping heart, oesophagus and pancreas. Hist. oat-cell.
3	1936	72	F	Bronchial carcinoma with heavy involvement of right tracheobronchial glands. Hist. oat-cell.
4	1941	52	M	Cherry-size nodule in lung. Diffuse pleural growth on left side with heavy involvement of tracheobronchial glands. Hist. alveolar.
5	1943	56	M	Bronchial carcinoma in right apex, enveloping subclavian artery and obliterating bronchus. Hist. oat-cell.
6	1943	51	M	Diffuse growth in right lung with greatly thickened pleura. Metastases in heart and vertebral bodies. Hist. alveolar.
7	1946	64	F	Diffuse growth in left lung. Patient feverish previous two months. Hist. columnar.
8	1946	48	M	Cavernous growth in right apex, with extensive involvement of mediastinal glands. Hist. alveolar. (Patient was heavy smoker of Virginian cigarettes).
9	1946	52	F	Nodular growth in left lower lobe with infiltration of lymphatics and diaphragm. Hist. adenocarcinoma.
10	1947	66	M	Diffuse growth in right lung apparently originating in bronchial mucosa. Severe involvement of mediastinum. Hist. oat-cell.
11	1948	47	M	Lower and middle lobe of right lung transformed by growth. Hist. adenocarcinoma.
12	1948	59	M	Small bronchial carcinoma with extensive metastases in mediastinal glands. Hist. bronchio-columnar.

the pleura" and "mediastinal sarcoma" or "oat-cell tumour"—are now included with pulmonary carcinomas. On the other hand, extrapulmonary tumours which have disappeared from their original site after irradiation may sometimes have metastasised in the lungs and been mistaken for primary lung carcinomas. Steiner (1944) and Passer and Holmes (1935) are among those who incline to the view that the increase is mainly apparent, but most authorities, including Huguennin (1928), Davidson (1930), Simons (1937), and Björk (1947), agree that there is an actual and considerable rise in the incidence.

FINDINGS IN ICELAND

The material for the present study was small, but its value is enhanced by the special circumstances in Iceland, where the isolated community live in conditions that are in many respects simpler and more transparent than in

TABLE II—SITES OF CARCINOMAS FOUND IN 1939 NECROPSIES

other countries, so that some of the agents which have been alleged to be responsible for lung carcinoma may be more accessible for evaluation in Iceland than elsewhere.

The study is based on the 1939 necropsies performed in Reykjavik from 1932 to 1948 inclusive. Most of these were done by me personally, and the rest by my assistants, usually under my supervision. There has consequently been a uniform approach to the subject, and the whole material has been critically reviewed for this purpose.

In this period we had 12 cases of primary lung carcinoma—11 diagnosed in our protocols and 1 added during this study, having originally been diagnosed as a mediastinal sarcoma but later found to be a pulmonary carcinoma of the oat-cell type. Of the 12 cases, only 3 were in females. This accords with the findings in other countries, where, according to Björk (1947), the preponderance in males has been found to range from 4.5:1 to 13.5:1.

The incidence of lung carcinoma in our necropsy material is 0.6%. The total number of malignant growths in this series was 417, so the proportion of lung cancers is 2.9%. On the basis of carcinomatous growths only, which numbered 337, the proportion is 3.5%. Details of the 12 cases are summarised in table I.

Table II shows the numbers of carcinomas found in different sites in our series and their sex distribution. Thus, in this 17 year period, cancer of the stomach was ten times as frequent as cancer of the lung. The survey indicates that in Iceland lung cancer is still a rare disease, the incidence being similar to that in many European countries at the beginning of the century.

DISCUSSION

Many conjectures have been advanced to explain the increased incidence of lung cancer. The inhalation of exhaust gases from motor vehicles and of vapour from

the tar products used in road making, and tobacco smoking, are most commonly blamed. The possible importance in this respect of respiratory infections, particularly influenza, has also been considered. Our experience in Iceland throws some light on the significance of each of these factors.

Respiratory Infections—These are highly prevalent in Iceland, especially in the winter. They disappear in the summer to reappear in the autumn, when the days are growing shorter. There is no doubt that bronchitis is more frequent in Iceland than in most civilised countries. If carcinoma tends to arise in organs in which inflammatory changes are most frequent, one would expect bronchial carcinoma to be particularly common in Iceland. But the fact that it is rare strongly suggests that there is no connection between the common respiratory infections and lung carcinoma.

Influenza—The view that the influenza epidemic of 1918 might have been a factor in the high incidence of lung carcinoma can also be refuted on the same grounds, for the population of Reykjavik were among the worst sufferers from that epidemic, the disease raging with a force hardly paralleled in any other country.

Tarred Roads—It is known that various tar products are carcinogenic, but it would be strange if they were much more carcinogenic for men than for women, and in all countries lung cancer shows this sex differentiation. Probst (1927) pointed out that the streets of Zürich were not tarred until 1920, but that lung carcinoma had shown a definite increase before that. In Reykjavik tarring of the streets also began about 1920, and since then most of the streets have been tarred. If the tarring had anything to do with the increased incidence of lung carcinoma we should expect a greater rise than we have found.

Contagion from Sheep—We have in Iceland a widespread disease among sheep, characterised by adenomatous growths in the lungs, the structure in some cases resembling carcinoma. Since this disease, which goes by the name of *jaagsækte*, is definitely contagious and produces lesions that are strikingly like some forms of diffuse carcinomatous growths, the possibility of its transfer to the human population has naturally been considered. In our material, however, we have never found human lungs resembling the *jaagsækte* lungs in sheep. Cases 4 and 7, and perhaps also case 5, were in a group by themselves in that the growths were of relatively short standing and appeared to have multiple centres of origin, possibly from the alveolar walls, as in *jaagsækte*, but the patients were townspeople who had had no known contact with sheep. In fact, our experience is very decidedly against there being any transfer of the sheep disease to man.

Tobacco—When I compare what I have seen of tobacco smoking in England and the U.S.A. with that in our country the difference is striking. Up to the last few years, when cigarette smoking has increased considerably, among both men and women, the consumption of tobacco, particularly in the form of cigarettes, has certainly been much less in Iceland than in most European countries and America.

* From Hutson (1937)

Roffo (1943) has shown that pulmonary carcinoma can be produced in rats by injecting tobacco tar into their lungs, according to Roffo this product is "strongly carcinogenic," so there is a sound experimental basis for the view that smoking predisposes to lung cancer. But if lung cancer is caused by inhaling a carcinogenic product of tobacco we would hardly expect the disease to start soon after the habit of smoking is acquired. From the miners at Schneeberg, of whom 60-70% die of lung cancer at one period, we may learn that lung cancer arising from the inhalation of a carcinogenic substance is a disease with a long period of incubation or, perhaps we should say, of preparation. Most of the miners who developed lung cancer had, according to Huguena (1928), been in the mines for about twenty five years and had reached 50 years of age, their average age being 55. If tobacco is a causal agent in lung carcinoma we might therefore expect to see it in people who have been smoking for twenty years or more, which in general would mean people over 40 years of age.

If we study the consumption of tobacco in various countries since the beginning of this century, we find a universal and considerable increase in the consumption of cigarettes, whereas the smoking of cigars has either decreased or only slightly increased. The consumption of snuff and chewing tobacco has decreased everywhere. Table III illustrates the increase in cigarette consumption in some European countries.

In England, where the incidence of lung carcinoma seems to be the highest in Europe, there is the highest consumption of cigarettes, and the annual total has increased greatly between 1913 and 1935. Assuming that lung carcinoma is determined by the inhalation of tobacco smoke during the previous fifty to twenty five years, then 1913-35 would correspond to the preparatory period of the lung carcinomas which have been making themselves increasingly apparent in the last two decades.

When we compare the per head consumption of cigarettes in Iceland with that in other countries (table IV) we see that in most of Europe it increased steadily between the two world wars, whereas in Iceland the figure was relatively low until the beginning of the second world war, when it rose enormously, and is apparently still increasing rapidly. Before 1926 the consumption in Iceland was under 0.24 lb per head, and the first two decades of the century it was considerably less. If we assume that twenty to twenty five years of tobacco smoking is necessary to produce cancer of the lungs, we should expect a very low rate of lung cancer in Iceland until 1960-65, when the rate would rise appreciably.

SUMMARY
